VIET NAM POPULATION PROJECTIONS

2024–2074

December, 2025

FOREWORD

The Intercensal Population and Housing Survey was conducted at 0:00 on 1 April 2024 under Decision No. 629/QĐ-TCTK dated 14 July 2023 issued by the Director of the General Statistics Office (now the National Statistics Office). This is a large-scale sample survey, covering approximately 20% of all enumeration areas nationwide (equivalent to 39,340 areas). The sample design ensures district-level representativeness (prior to administrative mergers for population size indicators and provincial-level representativeness for the remaining indicators.

The Survey collects essential information on population and demographics, population changes (births, deaths, and migration), and household living and housing conditions. This is the second Intercensal Survey conducted in Viet Nam, following the first carried out in 2014. The Survey aims to provide population and housing data to support the assessment of progress toward the 2021-2025 Socio-economic Development Plan; the development of population and housing policies for the 2026-2030 Socio-economic Development Plan; and the monitoring of the United Nations Sustainable Development Goals to which the Government of Viet Nam has committed.

To continue providing survey data and insights into future demographic trends and population structure, and to meet the growing needs of policy development, socio-economic planning, and workforce management at both national and local levels, the National Statistics Office is undertaking the "Viet Nam Population Projections, 2024-2074." This initiative aims to provide a reliable data foundation for policymakers and researchers in their processes of assessment, planning, and decision-making.

The report "Viet Nam Population Projections, 2024–2074" presents estimates of the population in 2024 based on the results of the 2024 Intercensal Population and Housing Survey, along with population projections for the whole country, urban and rural areas, the six socio-economic regions, and 34 centrally governed provinces and cities for the period 2024–2074. These projections are derived from baseline data from the 2024 Intercensal Population and Housing Survey and from assumptions about future changes in key demographic indicators, and were generated using the DAPPS 4.0 projection software developed by the U.S. Census Bureau.

The report "Viet Nam Population Projections, 2024–2074" was prepared by the National Statistics Office in collaboration with experts and with the technical support of the United Nations Population Fund (UNFPA). The National Statistics Office sincerely appreciates the cooperation and support of UNFPA in implementing the 2024 Intercensal Population and Housing Survey and in producing this publication.

The National Statistics Office would also like to express our gratitude to the experts and staff of the UNFPA Country Office in Viet Nam for their valuable contributions throughout the drafting and finalization of this report. Special thanks are extended to Mr. Tim Miller, chief demographer at PopTerra, for his support in training and guiding the use of the projection software, as well as for his insightful comments that contributed to the completion of the report.

The National Statistics Office is pleased to present the report "Viet Nam Population Projections, 2024–2074."

SECTION I

METHODOLOGICAL FRAMEWORK FOR POPULATION PROJECTIONS

I. PURPOSE OF POPULATION PROJECTIONS

Future trends in a country's population size and age-sex structure play a particularly important role in the formulation of development policies, as population is the foundation of all socio-economic development strategies. People are both the goal and the driving force of development; therefore, all policies directly or indirectly aim to improve the well-being and living conditions of the population. For this reason, comprehensive, timely, and accurate population information - including past, current, and projected data - is essential for designing and implementing policies effectively and appropriately. In this context, population projections become an indispensable tool, providing an objective basis for assessing population growth rates, trends, and dynamics. Such information is crucial for socio-economic development planning, resource allocation, public service provision, and for monitoring and evaluating the implementation of national development strategies and the Sustainable Development Goals.

Population projections are carried out to provide detailed data on the size and age-sex structure of the population for the entire country, the six socio-economic regions, 34 centrally governed provinces and cities (hereafter referred to as provinces), urban and rural areas, for the period 2024–2074. The projection results support policy planning at both national and local levels, the development and implementation of sectoral plans, and business and production management for enterprises and individuals. They also meet the information needs of organizations, researchers, and the general public for analysis and practical application.

Population projection work in Viet Nam has been carried out by the National Statistics Office for many years, based on data from the Population and Housing Censuses conducted in 1979, 1989, 1999, 2009, and 2019, as well as the 2014 Intercensal Population and Housing Survey (IPS). The results of these population projections provide estimates of population size for the entire country, socio-economic regions, and provinces prior to administrative mergers, disaggregated by urban and rural areas and by different age groups. These estimates constitute a valuable source of information for policy formulation, management, administration, and the monitoring and evaluation of development.

To maximize the use of the 2024 IPS data and to meet the growing information needs of users, the National Statistics Office has produced population projections to 2074 based on the 2024 IPS data and assumptions regarding the components of population change. In addition, the report analyzes several basic demographic characteristics of Viet Nam's population based on the projection results, in order to support long-term planning for human resource development.

II. DATA SOURCES, SCOPE, AND PROJECTION METHODS

1. Data sources

This report draws on data from the 2024 IPS on the size and age-sex structure of the population at the national level, for urban and rural areas, 6 socio-economic regions, and 34 provinces and cities. It assesses the quality of age reporting in the 2024 IPS and examines the suitability of these data for use as input in producing population projections.

2. Scope and Projection Period

Population projections are produced for the entire country, for national urban and rural areas, for the 6 socio-economic regions, and 34 provinces

Projection period:

- For the whole country: The projection period spans 50 years, from 2024 to 2074, and is divided into ten five-year intervals: 2024-2029, 2030-2034, …, 2070-2074.
- For urban and rural areas, the six socio-economic regions, and the 34 provinces: The projection period spans 25 years, from 2024 to 2049, and is divided into the following intervals: 2024-2029, 2030-2034, 2035-2039, 2040-2044, and 2045-2049.

3. Projection method

Population projections require the application of mathematical models based on current population data to identify future trends of fertility and mortality rates and migration. Demographers provide variants of low, medium, and high population projections based on different assumptions about how those rates will change in the future. Thus, the projections primarily depend on the accuracy of current baseline data, the more detailed and higher-quality the baseline data, the better the projection results will be. An extended period of projection will result in a higher rate of errors in the projection results because assumptions may lose accuracy over time.

The accuracy of the population projections also depends significantly on the relevance of assumptions made. Additionally, the population projection for the nation as a whole will be more accurate than for specific localities. Thus, it is necessary to project the national population independently from the local populations. Both national and sub-national populations are forecast using the cohort-component method, a standard demographic method that tracks people over time by age. These require estimates of the current age structure and assumptions about future mortality, fertility, and migration. By definition, the national projection should equal the sum of the sub-national projections. However, because the sub-national projections are produced separately from the national projection, their initial results may not add up exactly. In a second step, small proportional adjustments are made to the sub-national projections so that their sum matches the national projection exactly.

For the population projections of Viet Nam in the period 2024-2074, the GSO uses the cohort component method (Appendix 2) by sex and by 1-year age group with the open age group aged 80 and over (80 +). Although the survey date of the 2024 IPS was 1 April, in line with international practice-where average population is calculated using data as of 1 July-we adjusted the reference date to 1 July. This ensures consistency with international standards, provides a more accurate reflection of demographic indicators, and facilitates the monitoring of annual average statistics. Accordingly, the "year" referred to in the projections is understood as the calendar year (from January 1 to December 31), and the population figures for each year correspond to the mid-year population size, determined as of July 1.

DAPPS 4.0 software[1] (developed by the US Census Bureau is used for Viet Nam population projections for the period 2024-2074. Population projections are conducted in 2 phases: initially, for the whole country including all urban and rural areas; then, for the 6 socio-economic regions and 34 provinces. The results of national population projection by age and sex are used as control totals for the sub-national projections, ensuring that the total urban and rural projected population or 6 socio-economic regions equate with national projections. At the same time, when aggregated, the projected population sizes of provinces must equal the population projections of the corresponding socio-economic regions.

[1] *Demographic Analysis and Population Projection System 4.0*

III. ASSESSMENT OF DATA SOURCES USED FOR PROJECTIONS

The 2024 IPS is used to project population up to 2074. The accuracy of the base population data directly affects the quality of population projections as well as other demographic indicators. Therefore, it is necessary to apply specific techniques to assure data base accuracy and to determine any necessary revisions before forecasting.

1. Evaluation of the accuracy of information on population size in the 2024 IPS

The accuracy of the IPS population size is assessed by comparing the actual results of the 2014, 2019, and 2024 population surveys with the corresponding projected results produced under the medium-variant population projections developed previously. This comparison helps identify the magnitude of errors between projected and observed values, thereby reflecting the reliability and accuracy of the survey data as well as the suitability of the projection model used in each period. These findings serve as a basis for refining the model and adjusting the fertility, mortality, and migration assumptions for subsequent projection cycles.

Table 1.1.Observed and projected population from the 2014 and 2024 IPS and the 2019 Census

Thousand persons

	2009 Census	2014 IPS			2019 Census			2024 IPS		
	Observed	Observed	Projected (according to the 2009–2049 projection) - medium fertility scenario	Percentage difference	Observed	Projected (according to the 2014-2049 projection) - medium fertility scenario	Percentage difference	Observed	Projected (according to the 2019-2069) - medium fertility scenario	Percentage difference
Nation wide	85,847.0	90,493.4	90,654	-0.2	96,209.0	95,387.0	0.9	101,112.7	100,770	0.3
Male	42,413.1	44,618.7	44,939	0.7	47,881.1	47,405.6	1.0	50,346.0	50,335	0.0
Female	43,433.9	45,874.7	45,715	0.3	48,327.9	47,981.4	0.7	50,767.6	50,435	0.7

The results in Table 1.1 show a high level of consistency between the observed and the corresponding projection data. The forecasting errors at all three time points range from 0.2% to 0.9%, which is lower than the acceptable margin of error (±1%) recommended by the United Nations for medium-term population projections. Notably, the discrepancy between the projected and observed data for the 2024 IPS is only about 0.3%. This suggests a high level of accuracy and reliability of the population size information, and demonstrates that the assumptions on fertility, mortality, and migration used in the projection scenarios are appropriate and reflect the actual demographic trends in Viet Nam during the period 2009-2024.

In addition, the total population from the 2024 IPS is broadly consistent with Viet Nam's mid-2024 population estimate released by the United Nations Population Division in the "World Population Prospects 2024," which places the figure at 100.7 million (a difference of only around 0.4%). Likewise, the total population from the 2024 IPS differs by approximately 0.3% from the high-fertility variant estimate (100.8 million) presented in the report "Population Projections for 2019–2069," produced by the National Statistics Office in 2020 based on the results of the 2019 Population and Housing Census.

In addition, the results of the 2024 IPS were compiled by the National Statistics Office through a comprehensive data verification process involving all provinces and centrally governed cities nationwide. Local authorities confirmed that the figures accurately reflect actual population conditions and show a high level of consistency in both population size and structure, ensuring their reliability for use as the baseline population for projections.

Thus, the population size recorded in the 2024 IPS is highly consistent with statistical projections from various sources. This further suggests that the 2024 IPS produced high-quality and reliable results.

2. Assessment of the accuracy of age and sex reporting

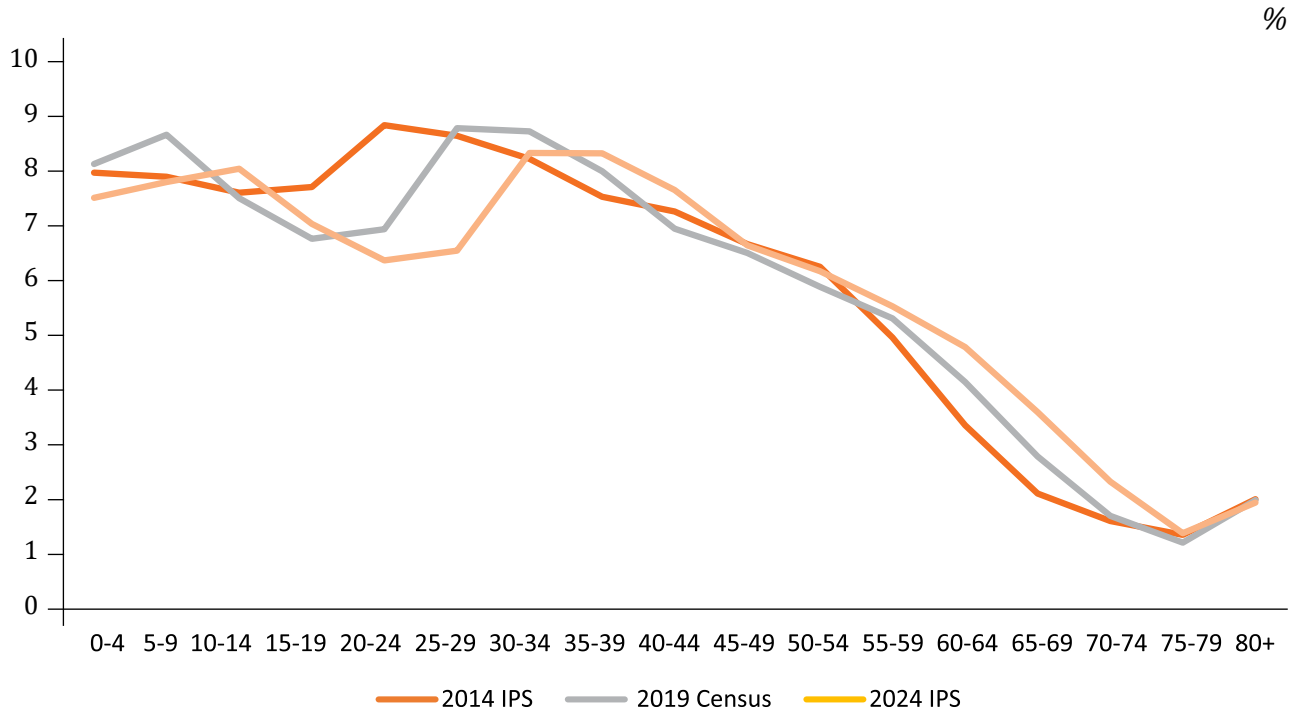
Although there are very strict regulations on the collection of age-related information in the statistical surveys, this information is sometimes subject to error. Common deviations include respondents who do not remember their exact age or that of family members. Some respondents intentionally misreport their age, according to certain trends. For instance, middle-aged people tend to under report their age, while the elderly tend to over report their age; some people like or dislike a certain number so they misreport their age. In particular, a number of respondents misrepresent their age in accordance with the trend of rounding up or down to numbers ending in 0 and 5. Misreporting information leads to an unusual concentration of population in certain preferred ages. This falsifies the data on population distribution by age. Therefore, a comparative evaluation of the sex age distribution between the last two censuses is applied to identify abnormalities and provide a basis on which to determine adjustment of the population structure by age.

2.1. Age and sex distribution

Figure 1.1 shows population distribution by five-year age groups for the 2019 Census and 2014 and 2024 IPS. The chart reflects significant variations in population structure from 2014 to 2024, and also shows a clear shift in the young, middle-aged, and older age groups.

Through the chart, it can be observed that the population distribution continues to exhibit the typical pattern of a population transitioning toward aging, reflected in the gradual narrowing of the proportions in younger age groups. The peaks and troughs along the curve for ages 5–39 in 2024 mirror the size of the corresponding cohorts in 2019 and 2014. These variations are mainly attributable to the effects of demographic events that occurred in the past, such as trends in fertility over the past two decades, including declining fertility driven by the trend toward later marriage and couples' increasing preference for having fewer children. When comparing the 2024 distribution with those of 2014 and 2019, the 2024 curve almost aligns in shape when shifted leftward by 10 years and 5 years, respectively. This indicates that the age structure of Viet Nam's population has maintained continuity across survey cycles, with differences mainly reflecting the natural progression of the age structure as the population ages.

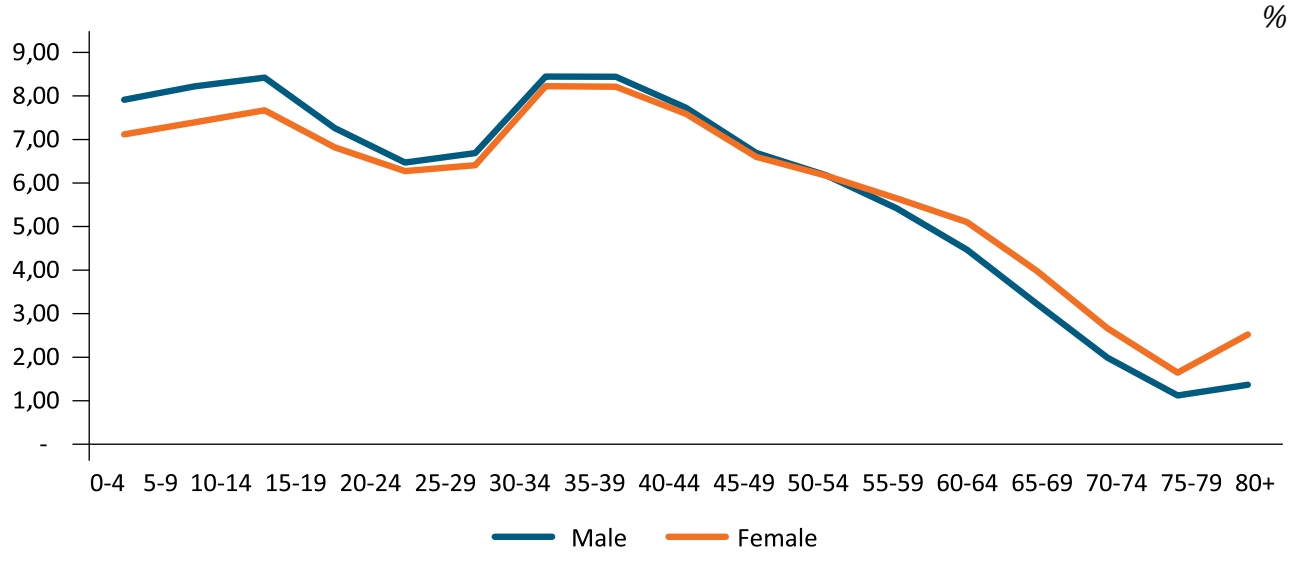
Figure 1.1: Population distribution by five-year age groups in the 2019 Census and the 2014 and 2024 IPS



2.2. Sex structure

Figure 1.2 depicts the age structure by sex in 2024. As the following chart indicates, population structure by age group was identical in both males and females. For the under the age of 20, there is a higher proportion of men than women, clearly reflecting the long-standing sex imbalance at birth in Viet Nam since the mid-2000s. For age groups 50 and above, the proportion of males is lower than that of females, mainly due to higher male mortality at older ages. This pattern is consistent with common demographic regularities.

Figure 1.2: Age structure of the male and female population, 2024 IPS



Thus, based on the graphical analysis, the age and sex information from the 2024 IPS can be considered reliable and of good quality.

3. Quality assessment index by age and sex

As recommended by the UN, there are three indices commonly used to evaluate the quality of age and sex information in demographic statistical surveys, including: the Whipple's index, the Myers' index and the UNI index.

The Whipple's index is used to measure the preference or dislike for ages ending in numbers 0 and 5. This index has a value ranging from 100 to 500. If the Whipple's index equals to 100, there is no age preference for the ages ending in number 0 or 5; if everyone reports their age ending in 0 and 5, the Whipple's index will equal to 500.

To classify the quality of age reporting by Whipple's index, the following standards are used (see United Nations, 1990; Iwunor, 1993).

Less than 105: Very good

105 to 110: Fairly good

110 to 125: Good

125 to 175: Poor

More than 175: Very poor

The Myers' index is used to measure preference or dislike for a certain age. In theory, in the absence of age heaping, the Myers' index equals 0; if all recorded ages end in the same unique ending digit, the Myers' index equals 90.

The UNI index (Age - sex accuracy index) incorporates accuracy measurements in reporting of sex ratios in different age groups; the quality of age reporting by age group is examined by the average values of the age ratios in the survey data. In order to evaluate the UNI index, the UN has set a three-level standard: under 20 is accurate; from 20 to 40 is relatively accurate and over 40 is very inaccurate.

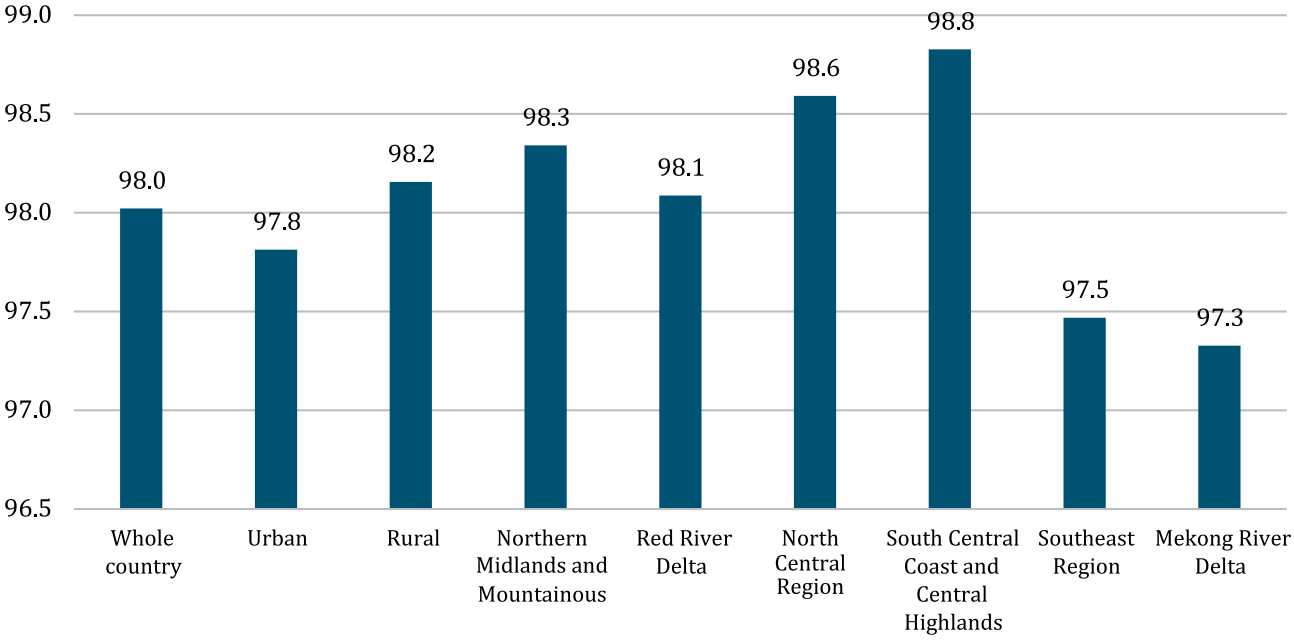
Calculation of these three indices on the 2024 IPS reveals reasonably good results for the evaluation, particularly that there is no concentration or preference at a certain age. Detailed results for the three indices in 2024 are presented in the following table.

Table 1.2: Quality assessment index of age information in the 2024 IPS

Quality assessment index	Value	Evaluation result
Age heaping index (Whipple)	98.0	Very good: No age rounding to the ages ending in 0 or 5
Index of age preference (Myers)	1.86	Almost no preference for a certain age
Age - sex accuracy index (UNI)	17.7	Accurate

Figure 1.3 presents the results of calculating Whipple's index for the nation as a whole, and urban, rural areas and socio-economic regions according to the results of the 2024 IPS. The results in Figure 1.3 show that there is almost no age rounding to the ages ending in 0 and 5 nationwide and in the regions in the 2024 IPS. In general, Whipple's index of the whole country and all regions are in the "very good" standard.

Figure 1.3: Whipple's index of the whole country, urban, rural area and regions, 2024 IPS



4. Adjustment of age structure of population in 2024 to be used as base population

Assessment of results from the 2024 IPS in terms of population size and structure by age and sex reveal it is relatively accurate. The same assessment method is applied to the age structure data for urban and rural areas, the six socio-economic regions, and the 34 provinces. The results show that the population size and age–sex structure of urban and rural areas, socio-economic regions, and provinces, as derived from the 2024 Intercensal Population Survey, accurately reflect the actual demographic situation at the local level. Therefore, the National Statistics Office does not adjust the age and sex structure, but retains the population structure as reported in the 2024 IPS

To facilitate the calculation and use of annual average population figures, the population data as of 1 April 2024 were adjusted to the reference date of 1 July 2024 using the MovePop tool developed by the United Nations. The population adjusted to this reference date is then used as the baseline population for the projection scenarios.

IV. ASSUMPTIONS

1. Assumption on fertility

The indicators reflecting fertility used in this projection study such as the Total Fertility Rate (TFR), the average number of children ever born to women of reproductive age, the age-specific fertility rates (ASFR), and the sex ratio at birth (SRB)- serve as the basis for formulating the fertility assumptions used to forecast Viet Nam's future population.

Assumptions about future fertility levels are developed primarily by examining current fertility patterns and the historical fertility transition that has led to today's levels, as well as considering the experiences of countries with similar cultural characteristics and comparable fertility trends to Viet Nam.

1.1. Total Fertility Rate (TFR)

Population projections for Viet Nam, based on current evidence on fertility trends, past fertility changes, and the United Nations' population projection methodologies presented in the World Population Prospects 2024, develop the projected trajectory of Viet Nam's fertility (TFR) for the period 2024 to 2074 under three variants: low, medium, and high.

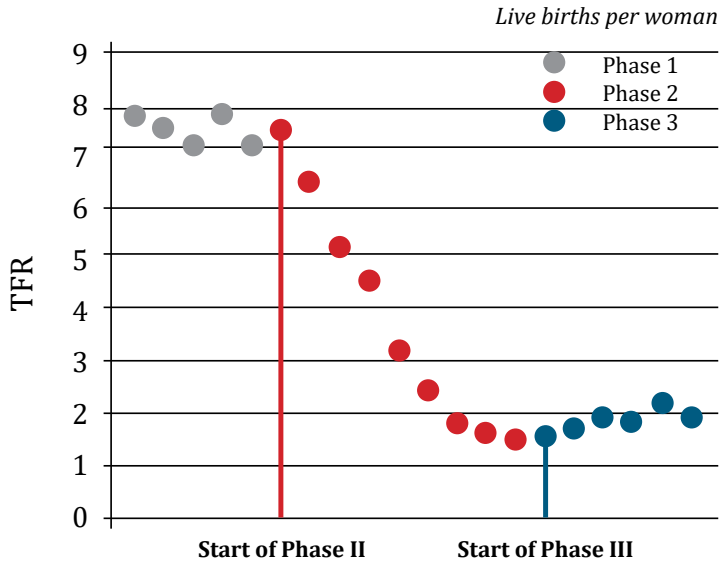
According to the United Nations, future fertility for each country is projected based on the theory of demographic transition. As stated in the World Population Prospects 2024 report, although the pace of fertility decline varies across countries, the overall pattern of fertility reduction generally follows a three-stage transition model.

Phase 1: The pre-transitional phase, characterized by high fertility with no clear trend.

Phase 2: The fertility transition phase, modeled using a double-logistic function within a Bayesian hierarchical model.

Phase 3: The post-transitional phase, characterized by low fertility, modeled using a first-order autoregressive time series model within a Bayesian hierarchical framework[2].

Figure 1.4: Schematic phases of the fertility transition



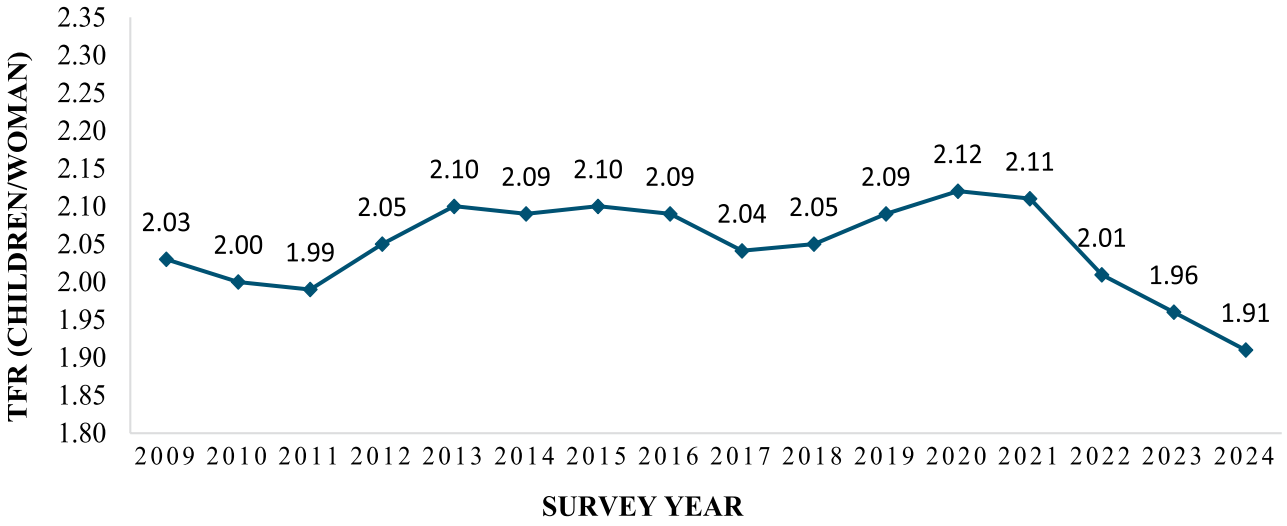
Source: Population Division of Department of Economic and Social Affairs, Methodology Report: World Population Prospects 2024, New York 2024, United Nations.

The United Nations' fertility transition model shows that the pace of fertility decline is typically fastest immediately after the decline begins. This rate generally slows as fertility falls to "intermediate" levels and slows further as it approaches the replacement level.

The 2024 IPS results show that the Total Fertility Rate (TFR) is 1.91 children per woman, below the replacement level. From 2009 to 2022, Vietnam's fertility remained relatively stable around the replacement level. However, in 2023–2024, it began to decline more rapidly, falling to 1.91 children per woman in 2024. According to the United Nations fertility transition model, Vietnam is now in the second stage of the transition and is nearing its end, with the current TFR already below the replacement level.

[2] *Source: https://population.un.org/*

Figure 1.5: Total Fertility Rate, 2009 – 2024



The United Nations projections of Viet Nam's TFR up to 2074 under three scenarios are based on a Bayesian hierarchical model (hereafter, the Bayesian model). This model forecasts Viet Nam's TFR by combining past and current fertility data with information from countries that have maintained stable low fertility levels.

According to these projections[3], half of projected TFR of Vietnam in 2074 are below 1.72 children per woman; 10% fall below 1.32; and another 10% exceed 2.13. Drawing on these UN estimates, the experiences of countries with sustained low fertility, and the policy goals set by the Government of Viet Nam, the National Statistics Office developed fertility assumptions under three variants-medium, high, and low. These assumptions were prepared for the population of the whole country, as well as for urban and rural areas, the six socio-economic regions, and 34 provinces and cities.

After determining the TFR values for the first year (2024) and the final year (2074) of the projection period, this forecast uses a tool developed by United Nations experts, the Excel file "tfr. trajectories.xls," which applies a normalized quadratic model with a transition period of 15 years (or 20, 25, or 30 years). This tool is then used to generate projected TFR values for each year up to the end of the projection horizon.

LOW VARIANT:

This variant assumes that national fertility trends will follow the declining trajectory projected by the United Nations for Viet Nam through 2074, in a context where policies aimed at maintaining replacement-level fertility are either not implemented or implemented ineffectively. Under this assumption, fertility in Viet Nam is projected to continue declining and to reach 1.45 children per woman by the end of the projection period. Specifically:

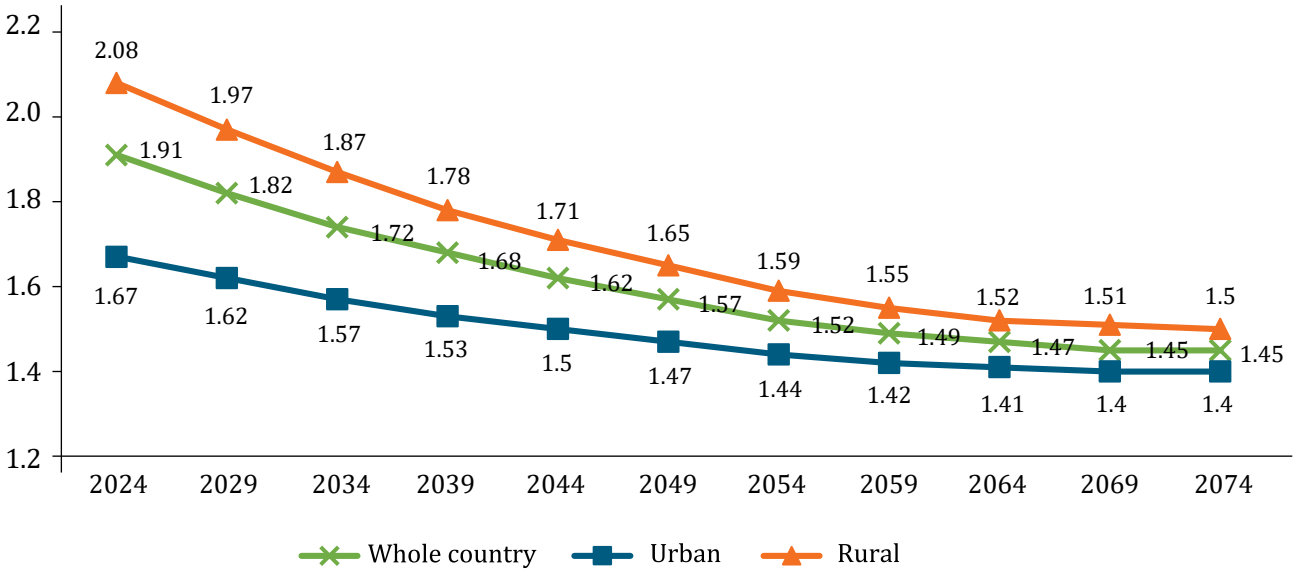
- National level: The total fertility rate over the period 2024–2074 is projected to decline continuously from 1.91 children per woman and to reach a low fertility level (TFR = 1.45 children per woman) by the end of the projection period (2074).
- For urban areas, fertility is projected to decline and stabilize at 1.4 children per woman by the end of the projection period; in rural areas, fertility is projected to decline sharply and stabilize at 1.5 children per woman by the end of the projection period.

[3] *Projection of the United Nations using Bayesian hierarchical model*

- For socio-economic regions and provinces with high fertility (TFR above 2.2 children per woman): Fertility is projected to decline sharply and reach 1.5 children per woman by the end of the projection period.
- For socio-economic regions and provinces with relatively high fertility (TFR from 2.0 to 2.2 children per woman): Fertility is projected to decline and reach 1.4 children per woman by the end of the projection period.
- For socio-economic regions and provinces with low fertility (TFR below 2.0 children per woman): Fertility is projected to decline and reach 1.3 children per woman by the end of the projection period.

Figure 1.6: Assumptions on the total fertility rate under the low variant for the whole country, and for urban and rural areas, 2024–2074

Children/woman



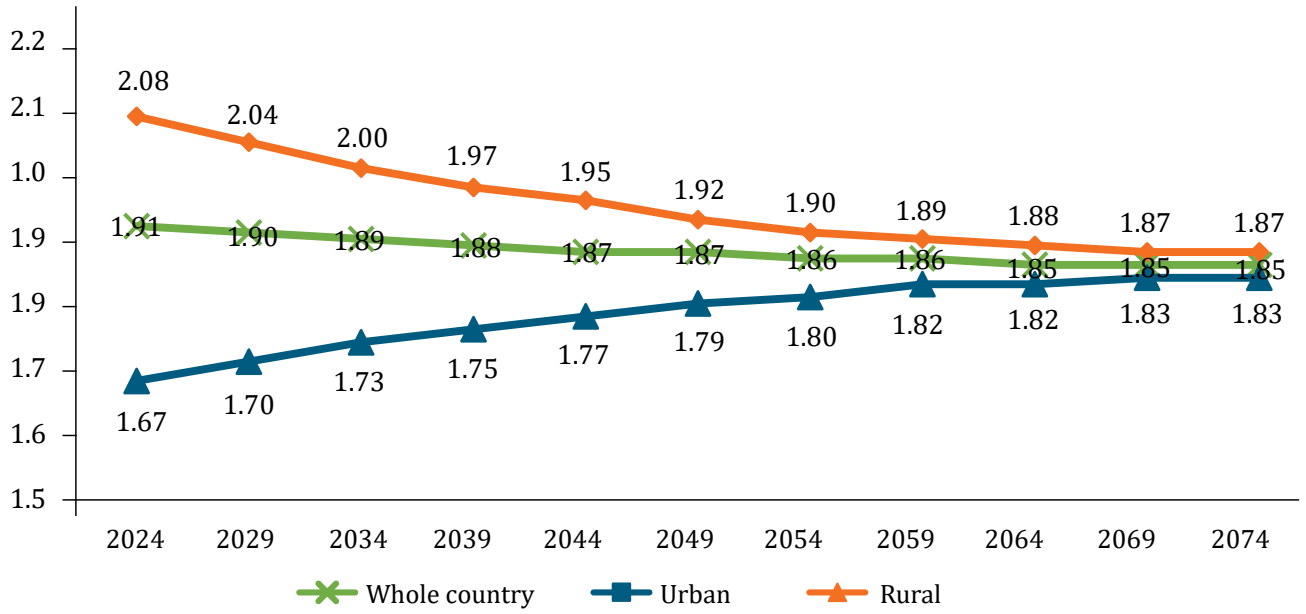
MEDIUM VARIANT:

Under the medium variant, government policies are expected to moderate the pace of decline from 2024 onward, keeping the TFR close to the replacement level through 2074. Fertility levels across the 6 socio-economic regions and the 34 provinces and cities follow this overall downward trend and are influenced by both national and local fertility-adjustment policies. Specifically:

- National level: Under the medium variant, Viet Nam's fertility is expected to follow a declining pattern from 2024 to 2074 (Figure 1.4), but the decline will be gradual. By the end of the projection period, the country's TFR is projected to reach 1.85 children per woman.
- Fertility in urban and rural areas is assumed to converge with the national level. Urban fertility is expected to increase slightly and stabilize at 1.83 children per woman by 2074, while rural fertility is projected to decline gradually and reach 1.87 by the end of the projection period.
- For socio-economic regions and provinces with high fertility (TFR above 2.2), fertility is expected to decline slightly and reach 2.01 children per woman by the end of the projection period.
- For socio-economic regions and provinces with low fertility (TFR below 2.0), fertility is expected to decline further and reach 1.5 children per woman by the end of the projection period.

Figure 1.7: Assumption of total fertility rate by medium variant for the whole country, urban and rural areas, 2024-2074.

Children/woman



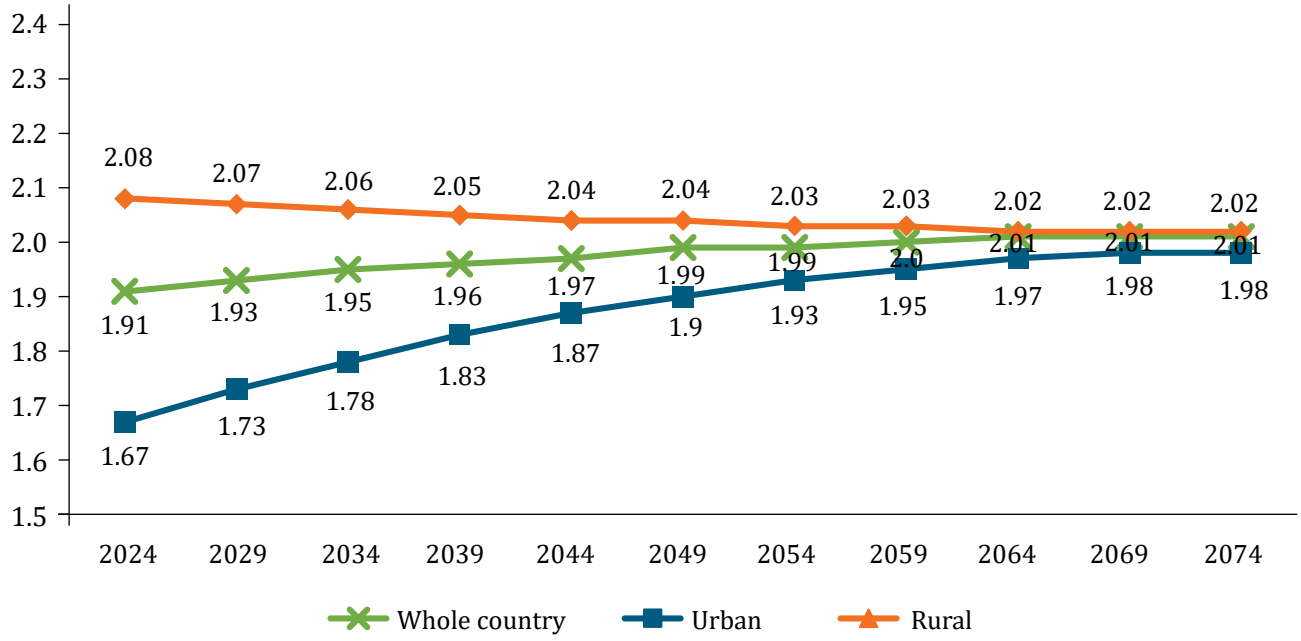
HIGH VARIANT

At present, the Party, the State, and the Government are working to develop policies and strategies to maintain the replacement fertility level. Based on this direction, the National Statistics Office assumes that Viet Nam's fertility will move toward to the replacement level.

- National level: From 2024 to 2074, Viet Nam's TFR is projected to rise slightly from 1.91 children per woman and reach TFR of 2.01 by the end of the projection period.
- For urban areas, fertility is projected to increase slightly and stabilize at 1.98 children per woman by the end of the projection period. For rural areas, fertility is expected to decline slowly and stabilize at 2.02 children per woman by 2074.
- For socio-economic regions and provinces with high fertility (TFR above 2.2), fertility is expected to decline slightly and reach 2.1 children per woman by the end of the projection period.
- For socio-economic regions and provinces with medium fertility levels (TFR between 2.0 and 2.2), fertility is expected to decline and reach 2.0 children per woman by the end of the projection period.
- For socio-economic regions and provinces with low fertility (TFR below 2.0), fertility is projected to reach 1.7 children per woman by the end of the projection period..

Figure 1.8: Assumption of total fertility rate by high variant for the whole country, urban and rural areas, 2024-2074

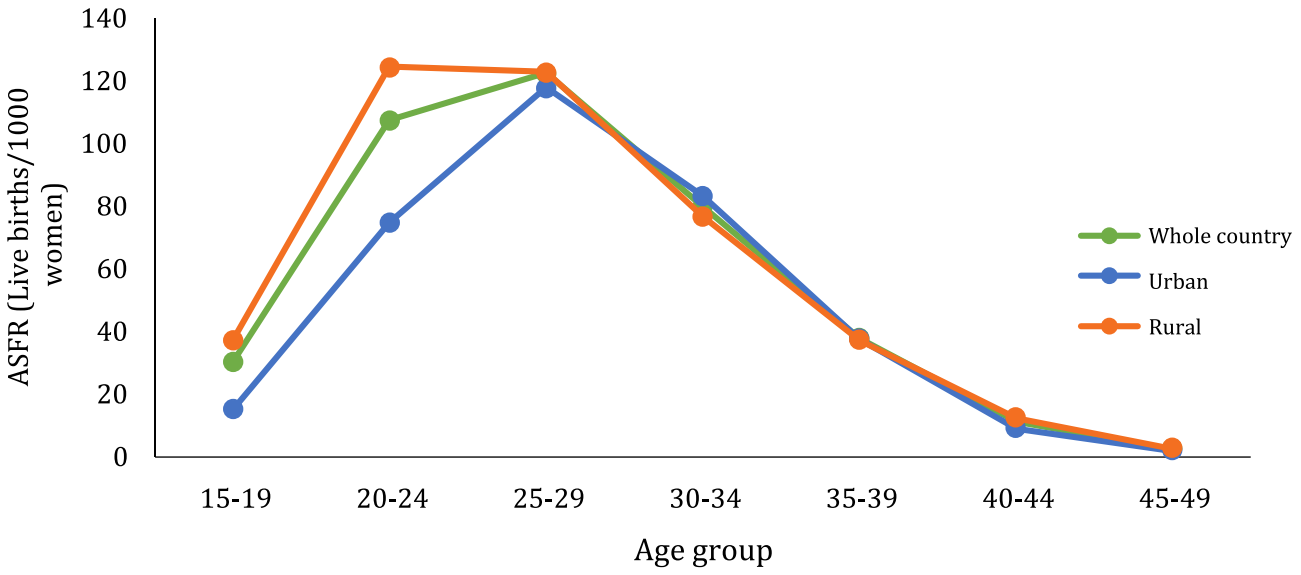
Children/woman



1.2. Fertility patterns

While total fertility rate changes over time, fertility patterns (also known as age-specific fertility rates) also change. As fertility levels fall below replacement level, the age pattern of fertility shifts from younger to older ages. However, the impact of the fertility pattern on the projected results is not significant. This projection is based on the assumption that the fertility age pattern of all forecasting units remains unchanged throughout the projection period.

Figure 1.9: Age-specific fertility rate (ASFR) by age group, urban and rural areas, 2024



1.3. Sex ratio at birth

In 2024, Viet Nam's sex ratio at birth (SRB) was 111.4 boys per 100 girls, significantly higher than the natural balance of around 106 boys per 100 girls. This elevated SRB has been observed in Viet Nam for many years (110.5 boys per 100 girls in 2009; 111.5 in 2019). Despite repeated warnings about the consequences of gender imbalance at birth and strong policy efforts to eliminate intentional sex selection during pregnancy, these measures have not yet been effective. The imbalance in the SRB has not been resolved.

Sex imbalance at birth will have a significant impact on population projection results, particularly on the sex composition of the population. Therefore, in this projection, the Statistics Bureau incorporates assumptions on the sex ratio at birth into the projection model.

The assumption on the sex ratio at birth (SRB) is based on the SRB time series of Viet Nam for the period 2009–2024, together with the Government's objectives and regulations aimed at reducing sex imbalance at birth and gradually bringing the SRB back to its natural equilibrium level. The SRB assumption follows a normalized quadratic model with a time-based transition phase. Under this assumption, Viet Nam's SRB is expected to decline slightly from 2024 to 2034. After 2034, the SRB is projected to decline due to the effects of policies aimed at reducing sex-selective practices and promoting gender equality. By 2044, the SRB is expected to move closer to the natural balance, reaching 107.9 boys per 100 girls; by the end of the projection period in 2074, it is projected to reach 106 boys per 100 girls. This assumption is applied to projections for the whole country as well as for urban and rural areas.

Table 1.3: Projected sex ratio at birth in Viet Nam, 2024 - 2074

Year	Projected SRB (boys/100 girls)
2024	111.4
2034	109.5
2044	107.9
2054	106.9
2064	106.2
2074	106.0

2. Assumption of mortality

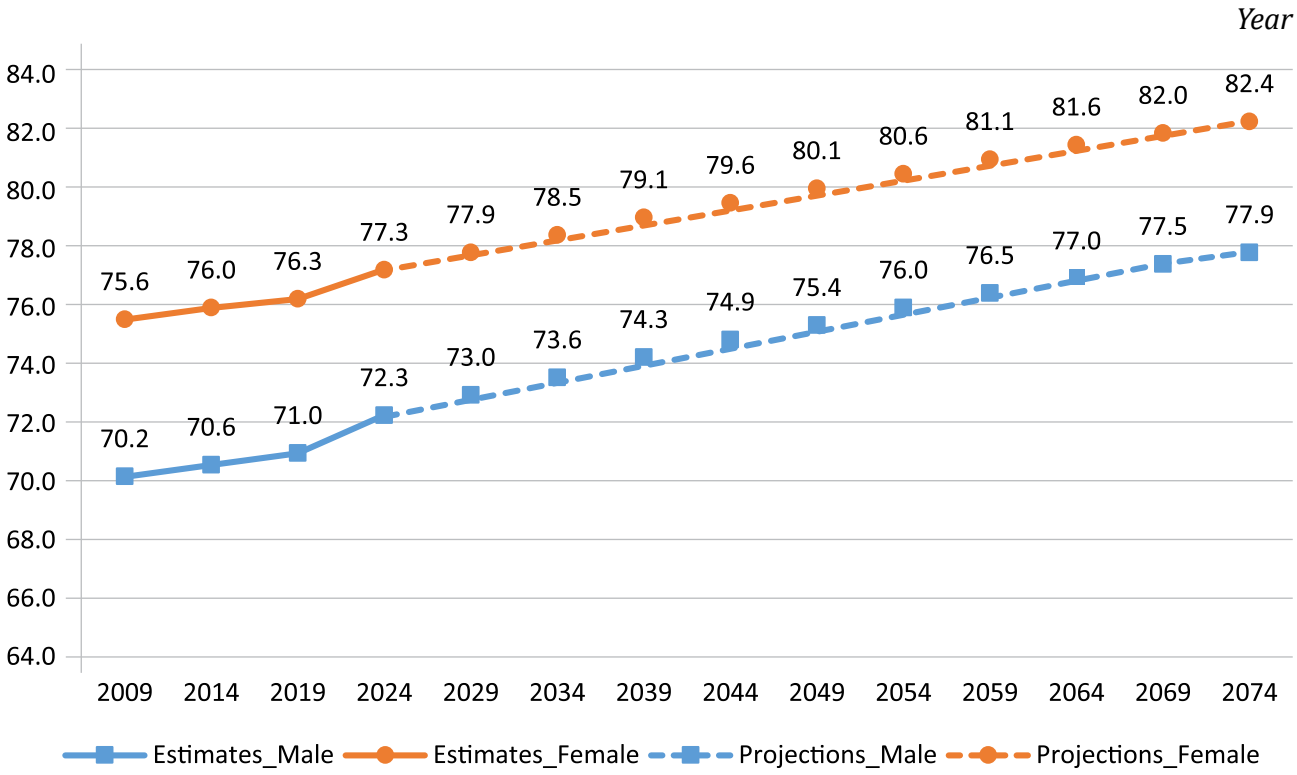
Mortality is one of the two components of natural population change and plays a key role in determining the rate of population growth. There are many indices measuring mortality including life expectancy at birth, mortality pattern, age-specific mortality rate, child mortality rate, maternal mortality ratio and life-table. The NSO bases predictions on life expectancy at birth (e0) and life-tables by sex to build assumptions on mortality for inclusion in the projection model.

2.1. Life expectancy at birth

Results from the 2024 IPS, the 2019 Census, and the annual Population Change and Family Planning Surveys all show that life expectancy at birth (e_0) in Viet Nam has steadily increased over time-from 68.2 years in 1999 to 73.6 years in 2019, and reaching 74.7 years in 2024. Compared with 2019, Viet Nam's life expectancy at birth increased by 1.1 years over a five-year period. Viet Nam's average life expectancy is higher than the global and ASEAN averages (73 years and

72 years, respectively). The life-expectancy gap between men and women in Viet Nam is about 5 years, which is comparable to the global average and higher than that of the ASEAN average (4 years)[4]. Improvements in public health care and socio-economic development in recent years have contributed to rising life expectancy. The 2024 IPS report provides updated calculations of life expectancy at birth. Mortality trends are estimated using the United Nations two-stage logistic model, in which mortality declines rapidly in the initial stage and slows in the later stage, based on international estimates of mortality levels and trends. Drawing on analyses of average annual increases in life expectancy at birth (e_0) by sex for different starting e_0 levels, the United Nations has identified typical improvement trajectories and uses these to project future life expectancy. The model allows for five possible rates of change in e_0: very rapid, rapid, medium, slow, and very slow improvement.

Figure 1.10: Life expectancy at birth for the whole country by sex, 2009–2024, and projections for 2029–2074



Based on historical increases in life expectancy and the improvement trajectories developed by the United Nations, the National Statistics Office assumes that life expectancy for both men and women at the national level, in urban and rural areas, in the socio-economic regions, and in the 34 provinces and cities will follow the slow-improvement variant. Details are provided in Annex 6 and 7.

2.2 Life table

In addition to life expectancy at birth, the component projection method using the DAPPS 4.0 software requires information on current age-specific death rates (ASDRs) and a model life table for the future age patterns of mortality.

Viet Nam's 2024 life-table by sex is calculated based on the results of the 2024 IPS and a model developed for Viet Nam since 1999 by international experts. The initial age-specific death rates used in the projections are derived from this life table data.

Note:

x: Age 0, 1-4, 5-9,...,80+

n: Number of ages in the group (1, 4, 5, 5, 5,....)

$_nL_x$: Number of person - years lived between age x and x+n

l_x: Number of alive people at the age x

$_nd_x$: Number of deaths between age x and x+n

$_nq_x$: Probability of dying between age x and x+n

$_np_x$: Probability of surviving between ages x and x+n

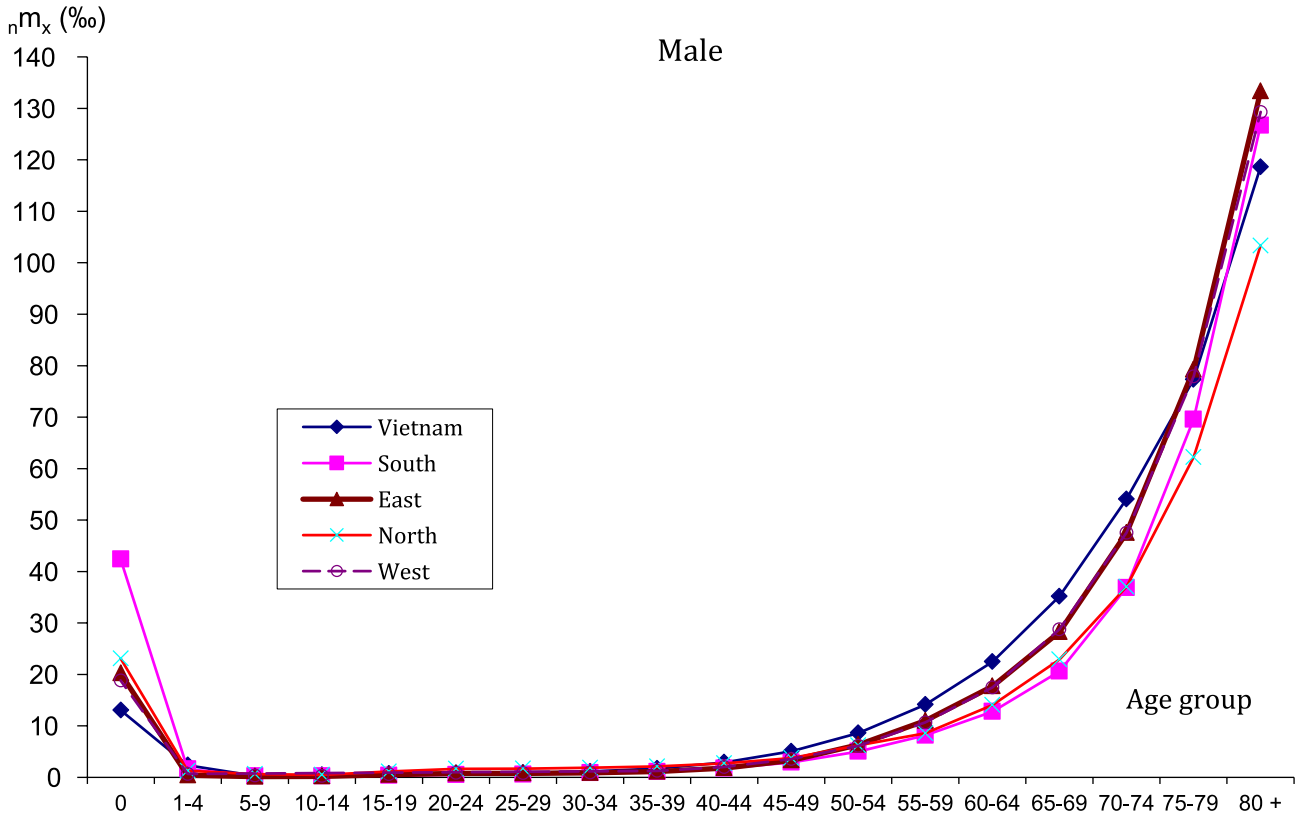
$_nm_x$: Age-specific death rate from age x to x+n

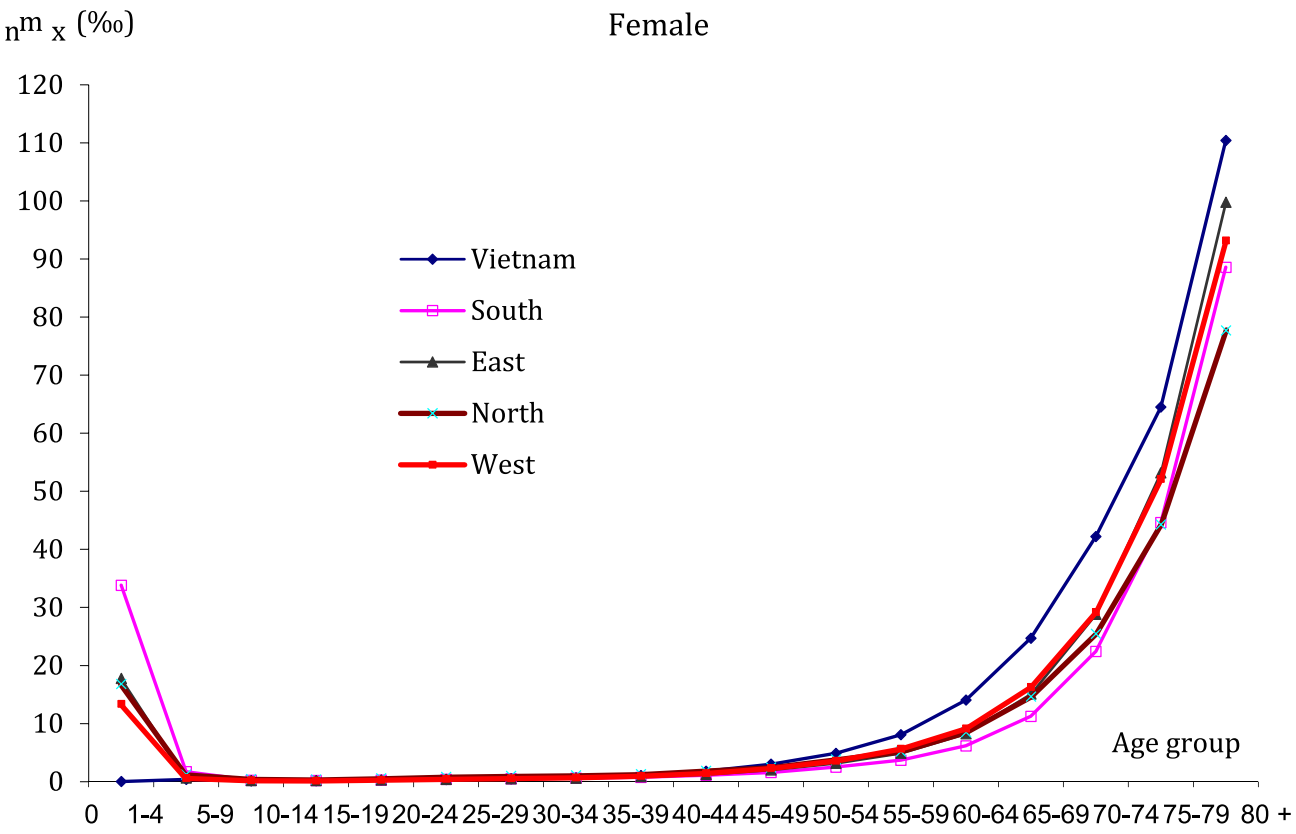
T_x: Number of person - years lived from age x onward

e_x: Survival expectancy at age x

Changes in mortality over time lead to corresponding shifts in the mortality model. This projection utilizes Viet Nam's age-sex mortality pattern using data from the 2024 IPS Survey. Figure 1.11 illustrates a graphical comparison of Viet Nam's mortality model with the four Coale-Demeny model life-table families-North, South, East, and West-constructed using the MORPARK 4.3 software and the MATCH tool.

Figure 1.11: Comparison of Viet Nam's age-specific death rates with the Coale–Demeny model: West, North, East, and South in 2024, by sex





The graphical comparison shows that Viet Nam's ASDR curve is fairly close to those of the North, South, East, and West model families. Using the least-squares method to compare Viet Nam's mortality pattern with the four Coale-Demeny model life-table families, the results indicate that for males, the West family yields the smallest least-squares value, while for females, the smallest is the East family. Specifically, the least-squares values when comparing with Coale-Demeny model are as follows:

North: Male = 0,0011	Female = 0,0020
South: Male = 0,0016	Female = 0,0021
East: Male = 0,0004	***Female = 0,0006***
West: Male = 0,0003	Female = 0,0007

Although the comparison results indicate that males are best fitted by the West model family and females by the East model family, the differences among the models are negligible in the context of Viet Nam's low and stable level of child mortality (declining from 16.0 to 11.3 deaths per 1,000 live births between 2009 and 2024). At the same time, the choice of mortality model does not substantially affect population projection results under the cohort-component method. For these reasons, the projection adopts the West model of the Coale-Demeny model life-table system for the ultimate age pattern of mortality. The projection shifts from the initial pattern based on the current Viet Nam life table to the ultimate age pattern based on the West model during the course of the projection as life expectancy increases.

3. Assumptions on migration

3.1. International migration

In this projection, net international migration is assumed to be zero, as the population of Viet Nam for statistical purposes includes all Vietnamese citizens, including those working, studying, or re-

siding abroad for permitted periods. Moreover, Viet Nam's net international migration in recent years has been very small and does not have a significant impact on population size. Therefore, net international migration is assumed to be zero in the projections.

3.2. Internal migration

3.2.1. Migration level

a. Urban-rural migration and urbanization

Two indices of level and rate are used to measure urbanization. The "urbanization level" is the proportion of the urban population extracted from the total population. The "urban growth" is the rate of the urban population changing over the time.

The UN has developed a model to evaluate the difference in population growth between urban and rural areas (URGD - Urban-Rural Growth Difference) and to monitor and forecast urbanization progress. This model assumes that both urban and rural populations are growing exponentially at their respective rates of ut and rt in each period. The ratio of the urban to rural population U_t/R_t therefore grows at rate $urgd = u_t - r_t$. Under this assumption, the proportion urban follows a logistic curve over time. In discrete annual form, the proportion urban at time t+1 can be written as:

$$\frac{U_{t+1}}{P_{t+1}} = \frac{(U_t/R_t) * e^{urgd}}{1 + (U_t/R_t)e^{urgd}}$$

Where:

u_t *=annual urban population growth rate*

r_t *= annual rural population growth rate*

urgd = difference between urban and rural growth rates = u_t- r_t

U_t*= urban population in year t*

R_t*= rural population in year t*

P_t*= total population in year t = U_t+R_t*

t = year

The logistic model describes urbanization as a form of bounded growth consisting of three stages: a slow initial increase, followed by rapid growth once the urban population share exceeds 30%. This continues until urbanization reaches above 50%, after which the pace gradually slows as it approaches natural and social limits. Viet Nam's urbanization data from 1989 to 2024 clearly reflects this pattern.

In the initial stage (1989-1999), the urban population share rose from 20.1% to 23.7%, indicating slow growth and reflecting a still-weak urban system, with urbanization not yet serving as a major driver of development. The 1999-2009 period marked a strong acceleration, with the share rising from 23.7% to 29.6%-an increase of nearly 6 percentage points over ten years-illustrating the fastest stage of the urbanization process, corresponding to the steepest segment of the logistic curve.

In the 2014–2024 stage, the urban population share continued to rise at a relatively high level, increasing from 32.8% to 38.2%, equivalent to 5.4 percentage points over ten years. This indicates that urbanization in Viet Nam is still progressing, but the pace has begun to slow.

Thus, the actual evolution of Viet Nam's urban population share shows that the logistic model is not only theoretically appropriate but also practically useful for describing and projecting the country's urbanization process in the medium and long term.

Based on the urban population share and the long-standing differences in urban and rural population growth rates in Viet Nam, and drawing on the United Nations urgd logistic curve model, the National Statistics Office has developed a trend for the urban population share according to differentials in urban and rural population growth rates as follows:

- The difference in the growth rates of the urban and rural populations (URGD) in Viet Nam during the first 25 years of the projection period (2024–2049) is assumed to be the same as in 2014–2024, at 2.33% per year.
- When the urban population share reaches 50% toward the end of the 2044–2049 period, the URGD is assumed to begin declining, reaching 1.83% per year by the final stage of the projection period.

The urban population share for each year throughout the projection period is estimated based on the logistic curve proposed by the United Nations[5]. When projecting urban and rural populations using the cohort-component method, net migration from rural to urban areas is determined so that population trends are consistent with the annual proportion urban.

Table 1.5: Average population growth rate by urban and rural areas, period 2014–2024 and projections for 2024–2074.

%

	Urban	Rural	Urban/ rural difference
2014-2024	2.62	0.28	2.33
2024-2034	1.92	-0.31	2.33
2034-2044	1.69	-0.64	2.33
2044-2054	1.30	-0.97	2.27
2054-2064	0.85	-1.13	1.98
2064-2074	0.62	-1.21	1.83

Note that the level of urban population growth of the projection periods takes into account people moving from rural to urban areas and people living in rural areas that develop into urban areas due to changes in administrative units from communes to townships and wards.

b. Interregional and interprovincial migrationh

The level of interregional and interprovincial migration is indicated by net migration, calculated from the 2024 IPS. The results show that in the five-year period 2019-2024, there were 1.5 million people aged 5 years and over migrating between provinces[6] and 1.1 million people migrating between regions[7].

Based on the calculated five-year net interprovincial migration derived from the 2024 IPS, provinces are classified into the following groups:

[5] *United Nations 1974, Manual VIII Methods for Projections of Urban and Rural Population, New York, Annex I (page 177).*

[6] *Migration is calculated for the 34 provinces after the mergers stipulated in Resolution 202/2025/QH15 on provincial consolidation in 2025.*

[7] *Regional migration is defined as migration between provinces that belong to different geographic regions.*

(i) Provinces with positive and stable net migration (more in-migration than out-migration) over time: including Ha Noi, Bac Ninh, Da Nang, Dong Nai, Ho Chi Minh City, and Tay Ninh.

(ii) Provinces with unstable trends: comprising provinces with irregular migration patterns, often reflecting exceptional fluctuations in the five years preceding the 2024 IPS, which result in net migration levels calculated from the 2024 survey that deviate markedly from those observed in previous survey rounds. This group includes Lai Chau, Thai Nguyen, and Hai Phong City.

(iii) Provinces with negative net migration (more out-migration than in-migration): this group is further divided into three subgroups:

Group 1: Provinces with slowly declining net migration (gradual decline), comprising provinces where net migration has decreased by less than 10% compared with the 2014 IPS. These provinces include Cao Bang, Son La, Lao Cai, Dien Bien, Lam Dong, Quang Ninh, and Ca Mau.

Group 2: Provinces with a moderate decline in net migration, comprising provinces where net migration has decreased by 10% to 50% compared with the 2014 IPS. These provinces include An Giang, Vinh Long, Tuyen Quang, Dong Thap, Lang Son, Can Tho City, Thanh Hoa, Dak Lak, Gia Lai, Quang Ngai, Nghe An, Quang Tri, Khanh Hoa, and Phu Tho.

Group 3: Provinces with a rapid decline in net migration, comprising provinces where net migration has decreased by more than 50%. These provinces include Ninh Binh, Ha Tinh, Hung Yen, and Hue City.

Based on the five-year migration levels from the 2024 IPS and the migration groupings described above, the modelling assumptions posit that migration will continue to occur at relatively high levels in the coming years, but will mainly take the form of intra-provincial migration. Interprovincial migration is expected to occur at lower levels and to gradually decline across successive five-year periods of the projection horizon, with specific assumptions applied to each group.

For provinces with negative net migration, the projections are built on the assumption that the magnitude of net migration will gradually decline over each five-year period of the projection horizon. The five-year net migration level derived from the 2024 Intercensal Population Survey is used as the baseline, and net migration in subsequent periods is adjusted according to the province-specific rate of decline corresponding to the above classification (rapid, slow, or moderate decline). This approach allows the projections to accurately reflect the ongoing downward trend in migration, while ensuring internal consistency and plausibility.

For the group of provinces with unstable trends, net migration in each five-year period of the projection horizon is assumed to be zero.

For provinces with positive net migration, the total net out-migration of provinces with negative net migration is reallocated to provinces in the positive net migration group. This allocation is based on each province's share of net migration within the group, as derived from the 2024 IPS. Such an allocation ensures that total net migration at the national level equals zero.

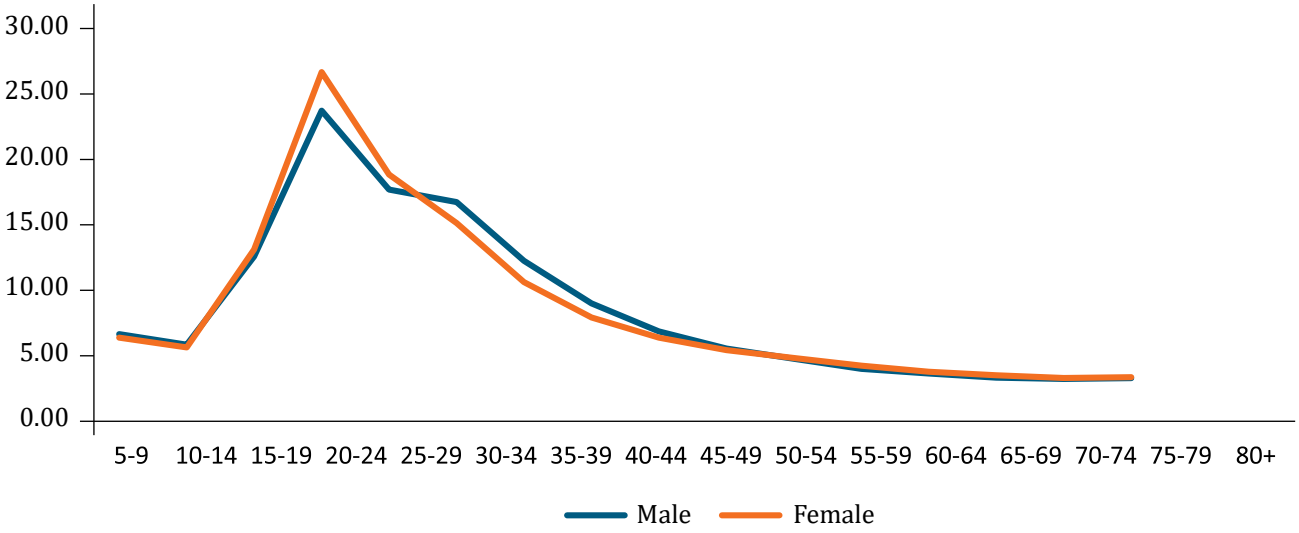
3.2.2. Migration Pattern

As migration level records the number of net migrants, the migration pattern reflects the age and sex distribution of the net migrants of the projection units (urban/rural, region/province).

Research on net migration of urban and rural areas, and provinces by age and sex shows a common form of the inverted U (low migration rate at a child age, then gradually increases and peaks in young adulthood; after the peak, the migration level decreases gradually with increasing age).

From the above comments, we assume that the age-based migration pattern will continue to be maintained throughout the projection period as observed in the 2024 IPS. Given that this age pattern is similar across areas and relatively stable over time, the projections are more sensitive to assumptions about the overall level of net migration than to small variations in its age distribution.

Figure 1.12. Migration pattern by age group and sex, 2024



3.2.3. Migration of the population aged 0-4

Although the results of the 2024 IPS do not provide information on migration for the 0–4 age group, migration data for this age group also need to be estimated for incorporation into the population projection model. To estimate migration for the 0–4 age group, the projections use the following formula:

$$NM(0\text{-}4) = 0.3*[NMMW(15\text{-}49)]$$

Where, *NM(0-4): Number of net migrants aged 0-4, ,*
NMMW(15-49): Number of net migration of married females aged 15-49.

This formula is based on the United Nations method for estimating migration in the 0-4 age group, with an adjustment to the multiplier applied to the number of married women aged 15-49 who are net migrants. Under the UN approach, the probability that a woman aged 15-49 gives birth during a five-year period is estimated by multiplying the General Fertility Rate (GFR) by 5. In many countries, the GFR is around 100 per 1,000, corresponding to a multiplier of approximately 0.5. In Viet Nam, the 2024 IPS shows a GFR of 53.6 per 1,000, which corresponds to a five-year birth probability of about 0.3.

This calculation reflects the assumption that roughly one-third of married women aged 15-49 who migrate during a five-year period will give birth at the place of destination, thereby generating the net migration size of the 0-4 age group.

SECTION 2:

RESULTS OF POPULATION PROJECTION

The results of population projection comprise two sets of data: (i) projected results for the whole country and for urban and rural areas; (ii) projected results for provinces and socio-economic regions.

Two sets of population projection results are produced under three variants: low, medium, and high. These variants differ in their assumptions regarding fertility levels and future fertility trends. Under these variants, by 2074, the total fertility rate reaches 2.01 births per woman in the high fertility variant, 1.85 in the medium fertility variant, and 1.45 in the low fertility variant.

I. Results of national population projection

1. Population size

Viet Nam's average population in 2024 was 101.3 million. By 2074, the population is projected to reach 114.2 million under the medium variant, 103.9 million under the low variant, and 118.5 million under the high variant. This means that over the 50-year period from 2024 to 2074, the population would increase by 12.7% and 17.0% under the medium and high variants, respectively, while under the low variant the increase would be only 2.5%.

Table 2.1: Projected population and annual average population growth rate by 3 variants, 2024-2074

	Low fertility variant		Medium fertility variant		High fertility variant	
	Population (Thous. persons)	Annual average population growth rate (%)	Population (Thous. persons)	Annual average population growth rate (%)	Population (Thous. persons)	Annual average population growth rate (%)
2024	101,344	-	101,344	-	101,344	-
2029	104,616	0.64	104,747	0.66	104,799	0.67
2034	107,163	0.48	107,670	0.55	107,873	0.58
2039	109,179	0.37	110,299	0.48	110,747	0.53
2044	110,592	0.26	112,537	0.40	113,315	0.46
2049	111,198	0.11	114,129	0.28	115,304	0.35
2054	110,909	-0.05	114,964	0.15	116,598	0.22
2059	109,856	-0.19	115,198	0.04	117,372	0.13
2064	108,245	-0.30	115,065	-0.02	117,878	0.09
2069	106,229	-0.38	114,714	-0.06	118,263	0.07
2074	103,892	-0.44	114,179	-0.09	118,543	0.05

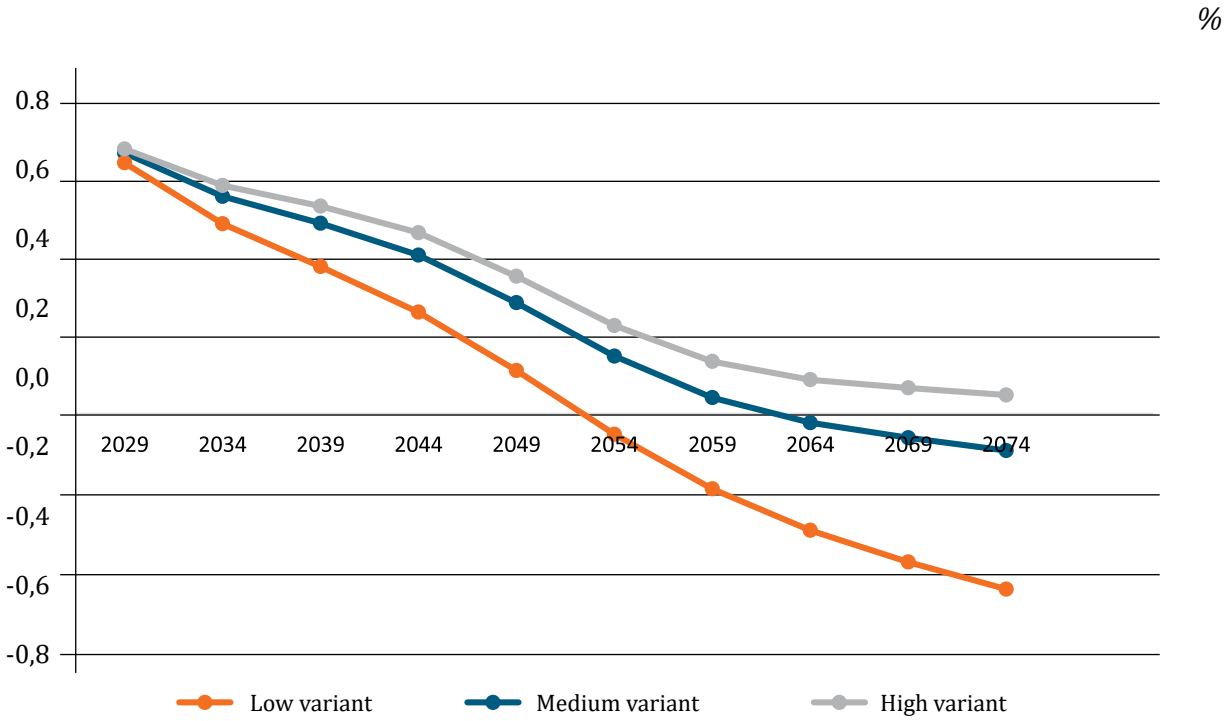
[8] *The annual population growth rate is the percentage change (increase or decrease) in the average population per year.*

Under the medium variant, Viet Nam's annual population growth rate is projected to be 0.66% during the first five years of the projection period (2024–2029). In the following years, the growth rate is expected to continue declining and reach a "zero-growth" state by 2059.

Under the low variant, if fertility declines as assumed, Viet Nam's population will begin to experience negative growth , with the rate of decline increasing over time. During 2049-2054, the population is projected to fall by an average of 0.05% per year. By the end of the projection period (2069-2074), the annual decline will reach 0.44%, equivalent to an average decrease of about 461,000 people per year.

At present, the Party, the State, and the Government are working to develop policies and strategies to maintain the replacement fertility level. Under the high variant, the National Statistics Office assumes that Viet Nam's fertility will return to 2.01 children per women by the end of the projection period. Under this variant, Viet Nam's population continues to grow slightly; during 2069–2074, the population increases by an average of 0.05% per year, equivalent to about 58,000 people annually.

Figure 2.1: Annual average population growth rate by three variants, 2024-2074



2. Sex structure

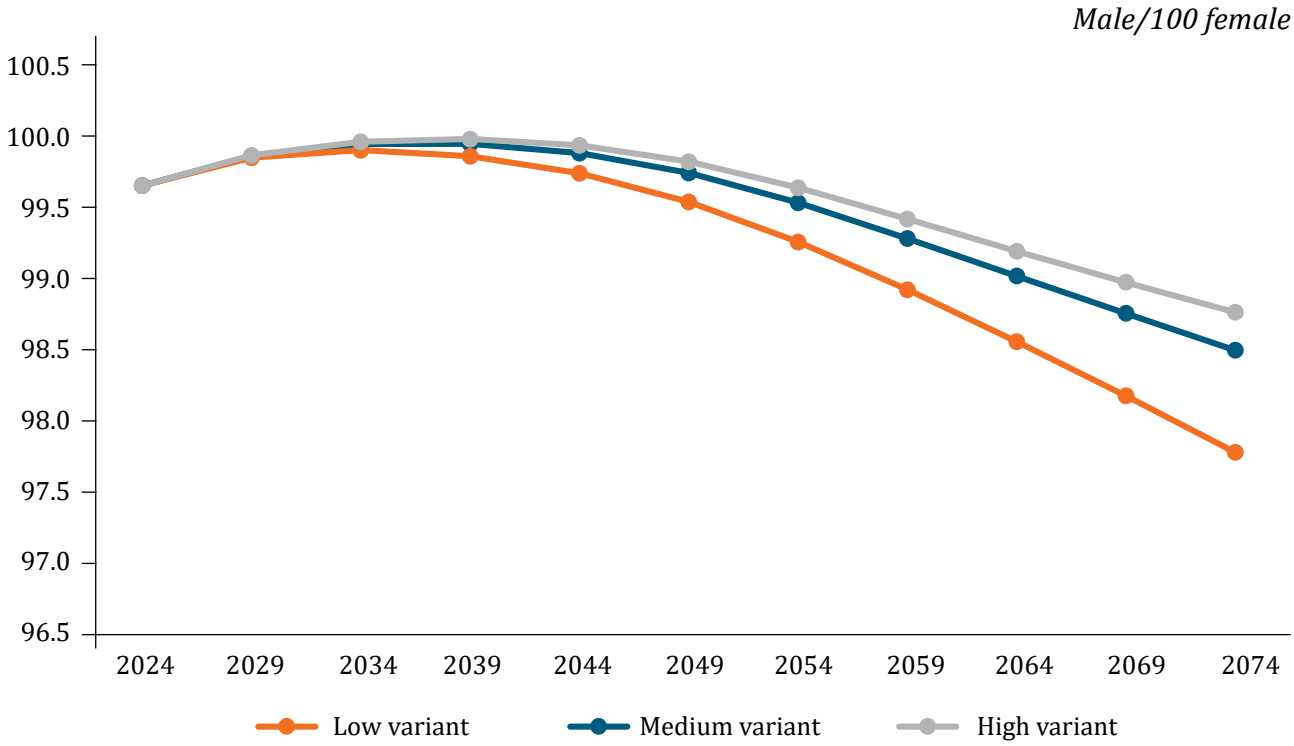
2.1. Sex ratio

The sex ratio of the population depends on the sex ratio at birth and on differences in mortality and net migration between males and females. In the national population projections, net international migration is assumed to be negligible; therefore, changes in the population sex ratio are driven mainly by the sex ratio at birth and by sex differentials in mortality.

The projections show that Viet Nam's population sex ratio will remain relatively balanced between males and females in the coming years. By 2029, all three fertility variants project a sex ratio of 99.8 males per 100 females. From 2034 onward, under the medium variant, the sex ratio rises slightly to 99.9 males per 100 females and remains around this level until the early 2040s, before gradually declining in later periods. It decreases from 99.7 in 2049 to 99.0 in 2064 and reaches 98.5 males per 100 females by 2074, indicating a long-term tendency toward a slightly higher number of females.

Because the sex ratio at birth is assumed to be identical across all projection variants, the differences between scenarios are small, although a clearer separation emerges toward the end of the projection period. By 2074, the high-fertility variant projects a sex ratio of 98.7 males per 100 females, compared with 98.5 under the medium variant and 97.8 under the low variant. In addition to the effects of fertility levels, the long-term declining trend in the sex ratio is also influenced by the fact that female life expectancy is projected to be about 4.5 years higher than that of males by the end of the projection period, leading to an increase in the proportion of females in older age groups.Overall, although the differences across variants are modest, all three scenarios show a gradual decline in the sex ratio over the long term- reflecting both the growing impact of longevity differences between men and women as well as the assumed decline in sex-ratio imbalance at birth.

Figure 2.2: Sex ratio of Viet Nam population by three variants, 2024-2074



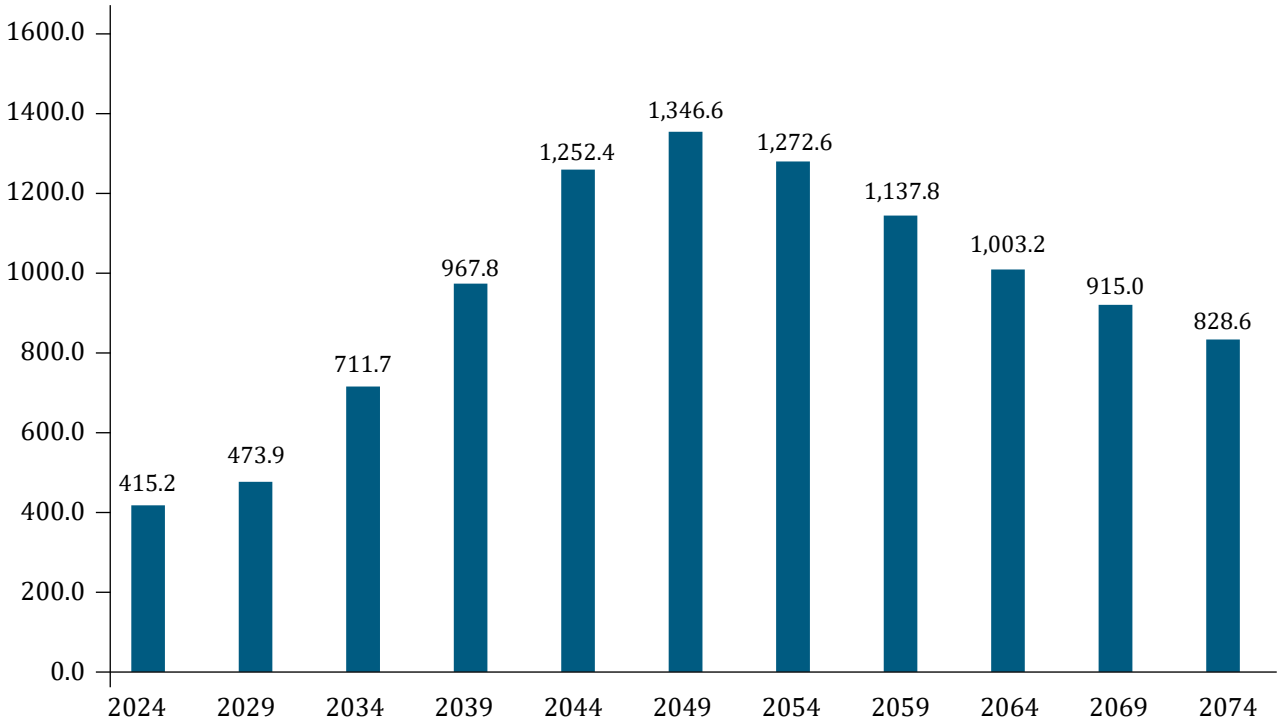
2.2. Demographic consequences of sex imbalance at birth situation

Vietnam's sex ratio at birth imbalance was first identified in the early 21st century, around 2005 to the present. This imbalance has led to changes in the population's gender structure and will result in a excess of men of marriageable age in the future. The 2024 Sex and Gender Survey continues to record an excess of men in the marriageable age group[9]. According to the medium population scenario, in 2029, for every 100 men of marriageable age (20-39 years), nearly 5 will be in surplus due to a shortage of women in the same age group-an outcome of the sex ratio at birth imbalance during the 2000s. By 2034, the number of men reaching marriageable age exceeds the number of women in the same age group by 711.7 thousand people, equivalent to 4.9% of the male population aged 20 to 39.

[9] *According to the Population Projection Report for Viet Nam for the period 2019–2069, a surplus of males within the marriageable age group (20–39 years) has already been recorded at the time of the 2019 Population and Housing Census.*

Figure 2.3: Number of excess males at the age of marriage due to sex imbalance at birth by medium fertility variant, 2024-2074

Thousand persons



After 2034, the excess of men and shortage of women in the marriageable age group (20-39 years) continues, with each subsequent year becoming more severe. By 2049, Vietnam will experience the highest shortage of women of marriageable age, lacking about 1.3 million women in this age group, equivalent to 8.7% of men aged 20-39.

After 2049, the excess of men in the marriageable ages shows signs of easing because the sex ratio at birth imbalance from 2034 onward is assumed to gradually decline. By 2074, the number of men reaching marriageable age exceeds the number of women of the same age by around 829 thousand people This indicates that the consequences of the sex ratio at birth imbalance during the first 30 years of the 21st century have led to changes in the gender structure of the population for the following 30 years, creating long-lasting social challenges in the subsequent decades.

A shortage of women of marriageable age may increase the vulnerability of certain groups of women in society, who already face higher risks of violence, sexual exploitation, and trafficking, in a context where competition among men to find partners is intensifying. These consequences require special attention in the formulation of population and gender policies, as well as in the protection of vulnerable groups.

3. Age structure of the population

3.1. Median age

The median age is an important demographic indicator that reflects how "old" or "young" a population is. It is the age at which 50% of the population is younger and 50% is older, and therefore is commonly used to assess the level and pace of population aging. Projections under all three variants show that the median age of Vietnam's population will increase continuously during 2024-2074 for both sexes, indicating that Vietnam is undergoing rapid population aging.

Table 2.2: Median age of the population by sex under the three variants, 2024-2074

Age

Year	Low variant		Medium variant		High variant	
	Male	Female	Male	Female	Male	Female
2024	33.1	35.1	33.1	35.1	33.1	35.1
2029	35.2	37.6	35.2	37.5	35.2	37.5
2034	36.8	39.8	36.5	39.7	36.5	39.6
2039	37.8	41.3	37.3	40.9	37.1	40.7
2044	38.8	42.4	38.1	41.7	37.8	41.4
2049	40.2	43.7	39.3	42.6	38.9	42.2
2054	42.1	45.2	40.8	43.9	40.3	43.4
2059	44.0	47.1	42.3	45.4	41.6	44.7
2064	45.8	49.0	43.7	46.7	42.8	45.8
2069	47.7	50.7	44.7	47.9	43.3	46.8
2074	49.2	52.5	45.1	48.6	43.4	46.9

According to the medium variant, the median age of Vietnam's population increases steadily over time. From 2024 to 2039, the median age for males rises from 33.1 to 37.3 years and for females from 35.1 to 40.9 years, equivalent to an increase of 4.2 years for males and 5.8 years for females over 15 years. In the subsequent period, the upward trend continues but at a slower pace; from 2039 to 2069, the male median age increases by an additional 7.4 years (from 37.3 to 44.7 years), while the female median age increases by 7.0 years (from 40.9 to 47.9 years). By the end of the projection period (2074), the male median age reaches 45.1 years and the female median age reaches 48.6 years, indicating a continued trend of population aging.

Under the low-fertility variant, the median age increases more rapidly because the number of children in the population declines sharply. By 2074, the median age reaches 49.2 years for males and 52.5 years for females, higher by 4.1 years and 3.9 years respectively compared with the medium variant. Over the entire period 2024-2074, the male median age increases by more than 16 years and the female median age by more than 17 years, indicating that low fertility strongly accelerates population aging and shifts the age structure more rapidly toward older age groups.

In contrast, under the high-fertility variant, the increase in median age occurs much more slowly. By 2074, the median age reaches 43.4 years for males and 46.9 years for females, lower by about 1.7-1.8 years compared with the medium variant and lower by around 5-6 years compared with the low-fertility variant. Over the entire 50-year projection period, the median age increases by only about 10-12 years for both males and females, indicating that higher fertility helps slow down the pace of population aging.

Overall, all three variants show that the median age of Vietnam's population increases over time, confirming that population aging is an irreversible trend. However, the pace of aging differs significantly across the variants: the low-fertility variant accelerates the aging process, while the high-fertility variant helps slow it down.

3.2. Population pyramid

The population pyramid is a common tool used to represent a combination of age and sex structures of the population in a geometric form (typically pyramidal shape). The population pyramid is divided into two parts by height line from the bottom to the top, where the right side denotes the female population and the left side denotes the male population. The shape of the population pyramid not only provides general information about the age and sex structure of the population at a specific time, but also is used to evaluate the transition in population structure over the years. The width of the youngest age group (pyramid base) reflects recent trends in births, while the width of the eldest age group (pyramid top) reflects both the size of cohorts born in the past (historical fertility) and the extent to which they have survived into old age (changes in mortality).

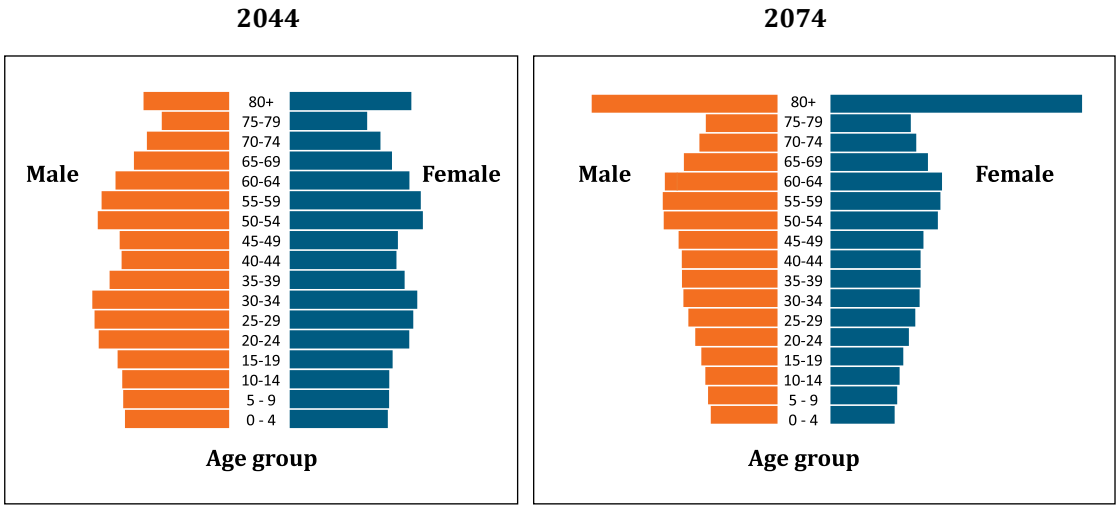
Figure 2.4 shows the Vietnam's population age pyramid in the first, middle and last year of the projection period by three fertility variants, clearly confirming a changing age structure bias towards an aging population. In 2024, the base of the population pyramid is relatively narrower than the older age groups, reflecting fertility remaining below replacement level. The middle part of the pyramid (ages 25-39) is still broad, indicating an abundant labor force and showing that Vietnam continues to be in the demographic dividend period. At the same time, the age groups 60 and above increase significantly, highlighting an increasingly evident trend of population aging.

In 2044, Vietnam's population pyramid becomes noticeably narrower at both the base and the middle compared with earlier years, reflecting sustained low fertility and the beginning decline of the working-age population. In contrast, the bars at the top of the pyramid-corresponding to those aged 65 and above-expand significantly compared with the present period, indicating a sharp increase in the share of older persons and showing that Vietnam has moved beyond the demographic dividend stage. The aging trend appears fairly consistent across all three projection variants, as prolonged low fertility continues to be the key factor driving changes in the future age structure.

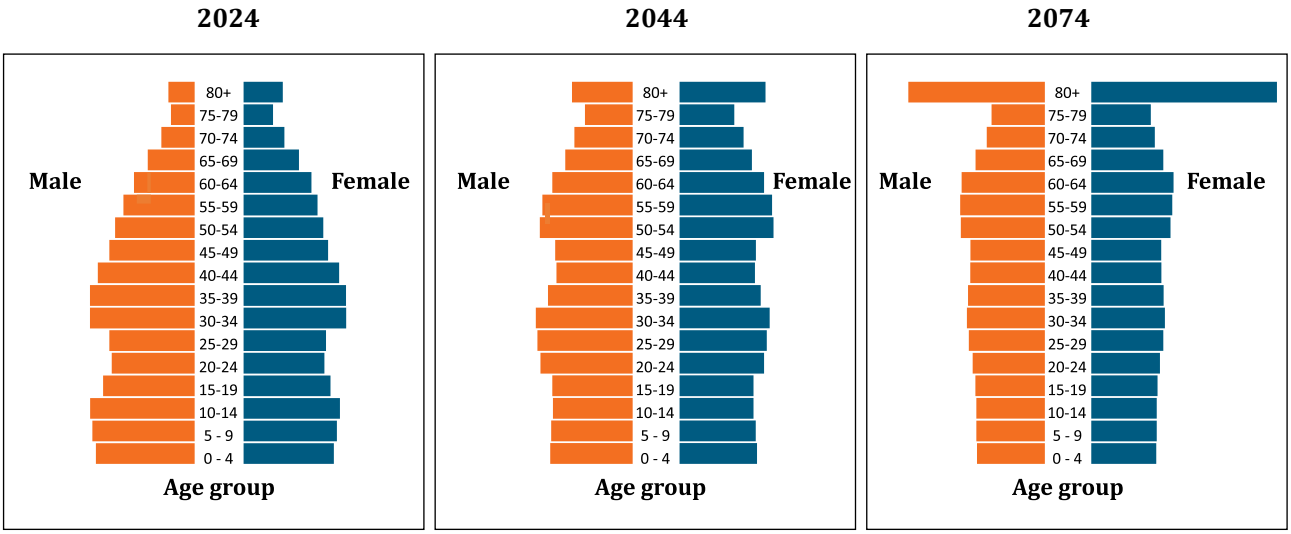
In 2074, Vietnam's population pyramid becomes sharply constricted at the base, reflecting a prolonged period of very low fertility. In contrast, the top of the pyramid expands markedly, with the 80-and-over group becoming the largest compared with all other age groups, indicating higher life expectancy and a very old population structure. By the end of the projection period, Vietnam's population has shifted to a deeply aged structure, with older persons making up a dominant share. This trend is most pronounced under the low-fertility variant and less severe under the high-fertility variant, but population aging remains a common pattern across all three projection variants.

Figure 2.4: Population pyramid, 2024, 2044 and 2074

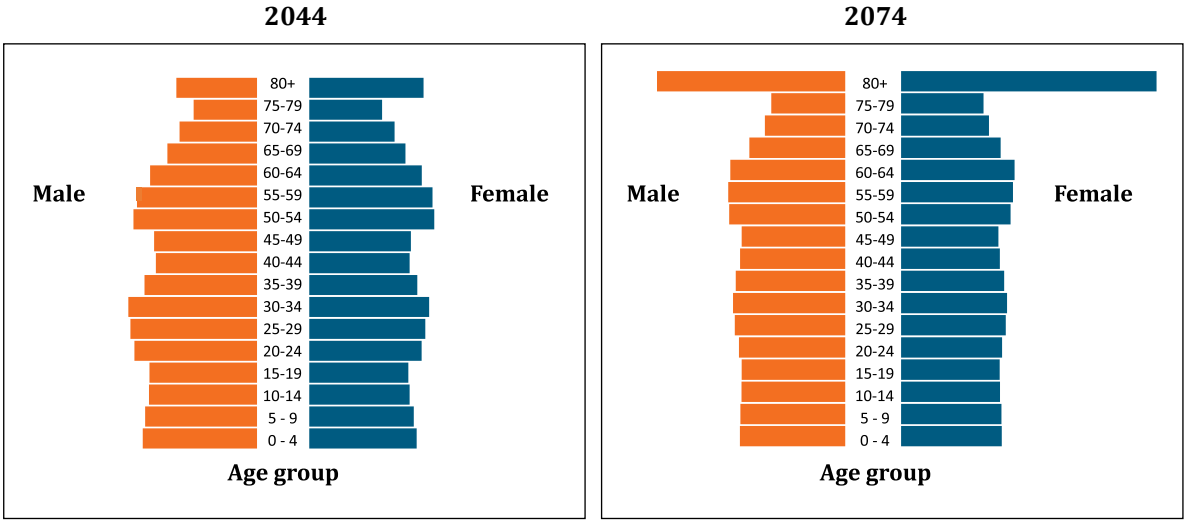
LOW VARIANT



MEDIUM VARIANT



HIGH VARIANT



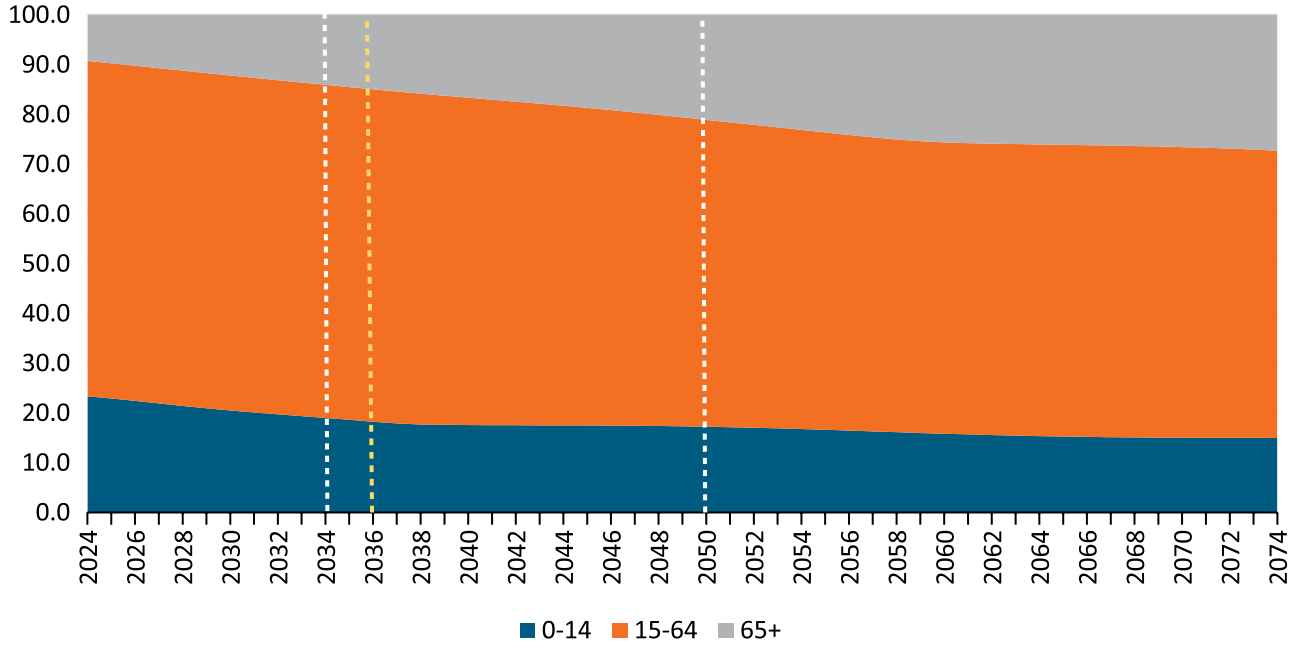
3.3. The demographic window of opportunity

Vietnam officially entered the period of the demographic window of opportunity in 2007, when the share of children (aged 0-14) fell below 30% and the share of older persons (aged 65 and above) fell below 15%[10]. During the demographic window of opportunity, the overall dependency ratio (the population aged 0-14 and 65+ relative to the population aged 15-64) typically remains below 50%, meaning that every two people of working age (15-64) support one dependent person (under 15 or 65 and above).

Data show that Vietnam will remain in the demographic window of opportunity during 2024-2035, as the share of children (aged 0-14) consistently stays below 30% and the share of older persons (aged 65 and above) remains below 15%. Throughout this period, the working-age population (aged 15-64) stays at a very high level, declining only slightly from 67.4% in 2024 to 66.9% in 2035, creating favorable conditions for economic growth and human resource development.

By 2036, the share of older persons rises to 15.0%, surpassing for the first time the threshold used to define the demographic window of opportunity. This is considered the point at which Vietnam ends its demographic window of opportunity . After this milestone, Vietnam's population structure transitions into a phase of rapid aging, reflected in the continuous increase in the proportion of people aged 65 and above and the gradual decline in the share of the working-age population over time.

Figure 2.5: Projected demographic window of opportunity, medium variant



3.4. The period of aged and super-aged population structure

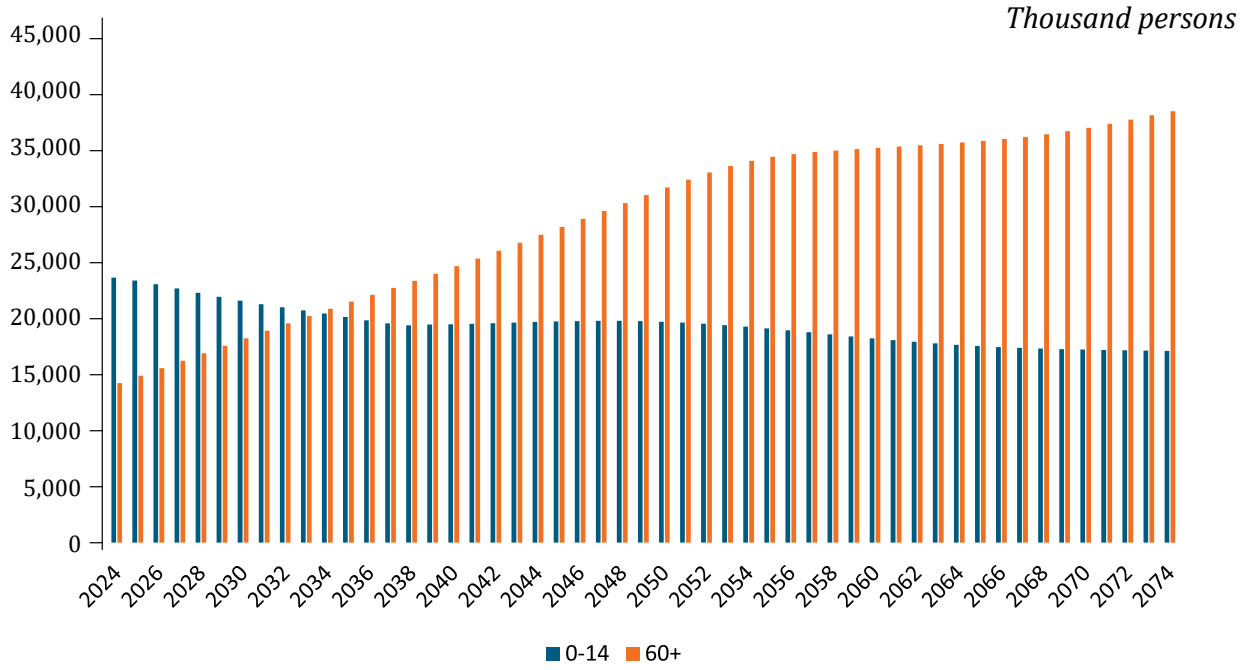
Under the medium variant, throughout the projection period, Vietnam's older population (aged 65 and above) increases very rapidly, rising from 9.3 million in 2024 to 20.5 million in 2044 and reaching 31.2 million in 2074. During this period, Vietnam's aging index (the percentage ratio of the population aged 60 and above to the population under age 15) rises continuously and at a very fast pace. In 2024, the aging index reaches 60.2%, meaning that for every 100 children there are about 60 older persons. By the end of the projection period, this index climbs to 224.9%, meaning that for every 100 children there are nearly 225 older persons. Over half a century, the aging index increases

[10] *According to the definition of the United Nations Population Fund in the report "Harnessing the Demographic Dividend in Viet Nam – Opportunities, Challenges and Policy Recommendations: the period of "demographic dividend" occurs when the percentage of children (0-14 years old) is lower than 30% and the percentage of elderly (65 years old and over) is lower than 15%.*

by about 3.7 times. This means that while in 2024 there is roughly 1 older person for every 2 children, by 2074 there will be about 4 older persons for every 2 children, reflecting the growing pressure of population aging on the working-age population and the social security system. By 2034, Viet Nam will cross a major demographic threshold, with older persons (aged 60+) outnumbering children (ages 0-14).

Thus, under the medium variant, Vietnam enters the aged population period[11] in 2034, when the share of the population aged 65 and above reaches 14%. From 2034 to 2036, Vietnam simultaneously remains in the demographic dividend period and enters the aged population stage. Vietnam's aged population period will last 16 years, from 2034 to 2049. After this stage, from 2050 to 2074, Vietnam will transition into a super-aged population structure, corresponding to the share of people aged 65 and above reaching above 21.%. The proportion of older persons (65+) in 2050 and 2074 accounts for 21.1% and 27.3% of the total population, respectively.

Figure 2.6: Population aged 0-14 and 60+, medium variant, 2024-2074



II. Projection results for urban and rural areas

Table 2.3 shows that Vietnam's urban population continues to grow strongly throughout the entire period 2024-2074, while the rural population steadily declines over time. Under the medium variant, the urban population increases from 38.7 million in 2024[12] to 74.2 million in 2074. Thus, over 50 years, Vietnam's urban population is projected to grow by an additional 35.5 million people, an average increase of about 710 thousand people per year. In the first two decades of the projection period, the differences across the three fertility variants are minimal, indicating that the main driver of urban population growth is rural-to-urban migration rather than fertility changes. After 2040, the pace of urban population growth begins to slow due to declining fertility and the shrinking size of younger cohorts entering childbearing ages. During this stage, differences between the projection variants become more pronounced: by 2074, the urban population under the low-fertility variant reaches about 67.6 million, while under the high-fertility variant it may rise to 76.9 million.

[11] Following international practice, a population is classified as "aged" when its population aged 65 and over accounts for 14 per cent and more of the total population, and a population is classified as "super aged" when its population aged 65 and over accounts for 21 per cent or more of the total population

[12] The share of the urban population is adjusted based on the 2024 IPS results to ensure consistency with the administrative unit classification stipulated in Decision No. 19/2025/QD-TTg, which promulgates the list and codes of Vietnam's administrative units.

Table 2.3: Projected urban and rural populations and average annual population growth rate, 2024-2074

	Low variant		Medium variant		High variant

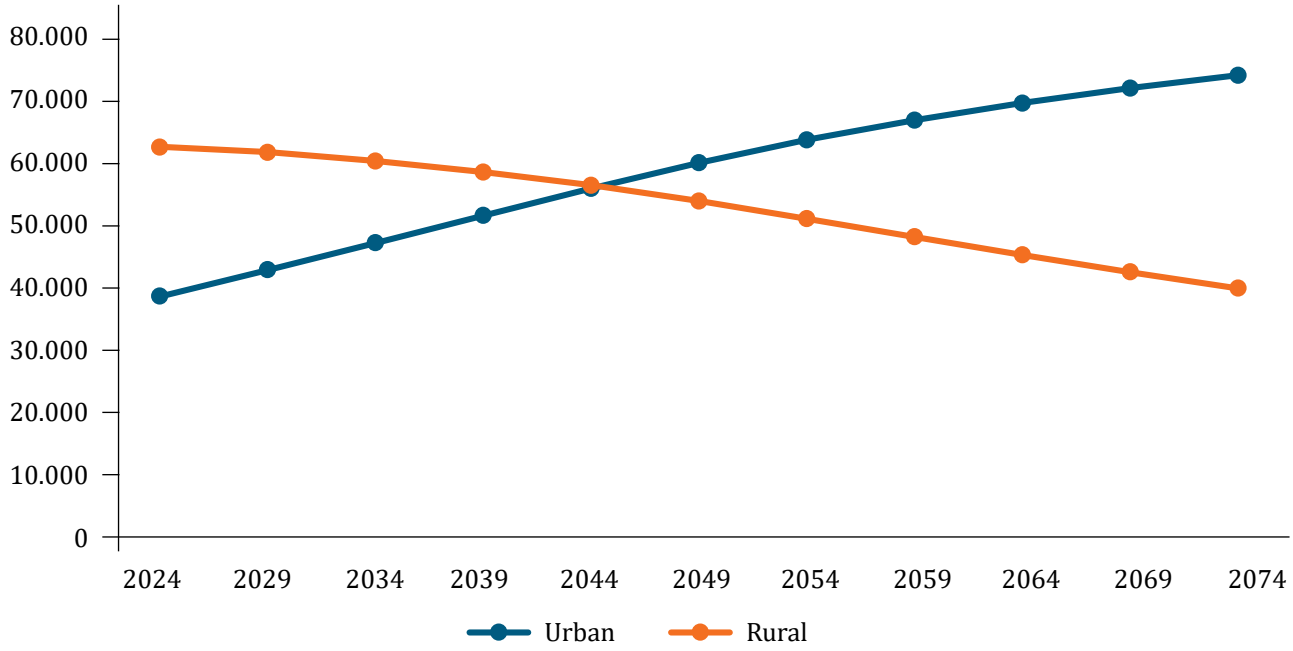
2044	55,661	-0.86	56,520	-0.73	56,893	-0.68
2049	52,732	-1.08	53,985	-0.92	54,530	-0.85
2054	49,488	-1.27	51,150	-1.08	51,877	-1.00
2059	46,132	-1.40	48,227	-1.18	49,154	-1.08
2064	42,764	-1.52	45,341	-1.23	46,495	-1.11
2069	39,481	-1.60	42,592	-1.25	44,006	-1.10
2074	36,305	-1.68	39,980	-1.27	41,675	-1.09

According to projections under all three fertility variants, Vietnam's urbanization rate will increase rapidly in the early years of the projection period. By 2045, the share of the population living in urban areas reaches around 50%, marking the point at which the urban and rural populations become equal. Urbanization continues steadily in the second half of the projection period, and by 2074 the urban population share reaches 65.0% under the medium-fertility variant, 65.1% under the high-fertility variant, and 64.8% under the low-fertility variant.

Figure 2.7 : Urban and rural population size, 2024-2074

Thousand persons



III. Projection results for socio-economic regions

Although projections are conducted for 10 periods from 2024 to 2074, the more detailed and longer-term the projections are, the less accurate they become, so the projection results for the regions are provided only up to 2049 (covering a 25-year period).

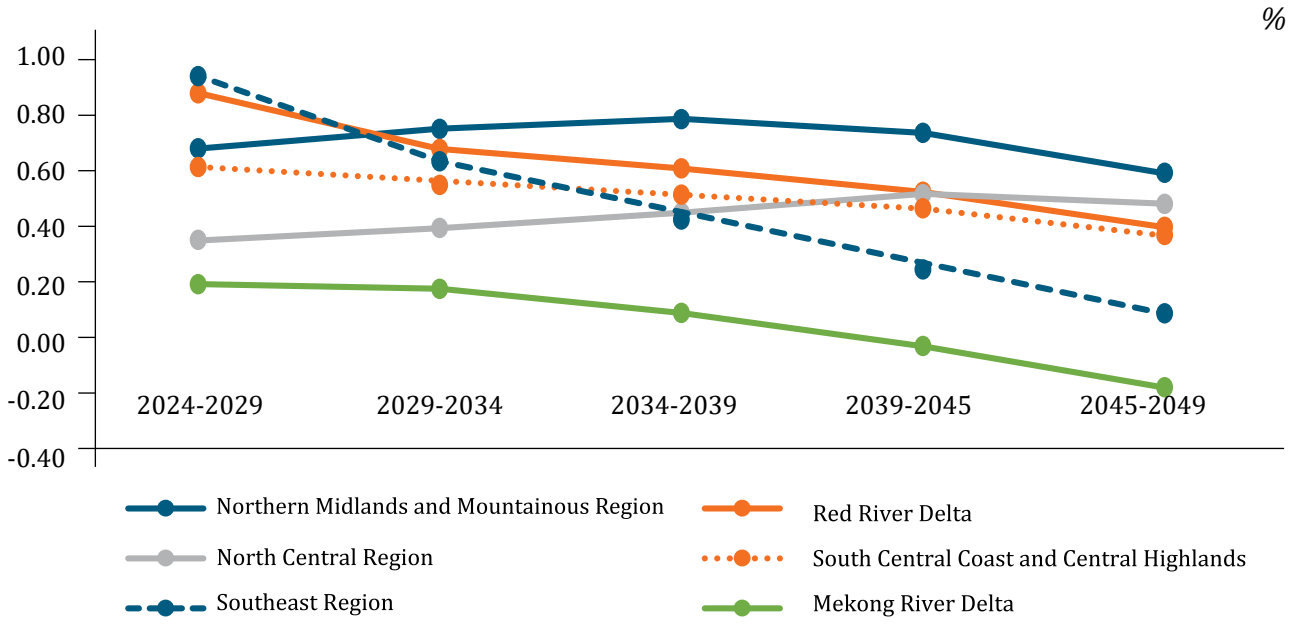
Table 2.4: Projected population of socio-economic regions under the medium variant, 2024-2049

Thousand persons

	2024	2029	2034	2039	2045	2049
Nation wide	101,343.8	104,747.0	107,670.2	110,299.0	112,537.0	114,129.4
Northern Midlands and Mountainous Region	12,601.6	13,037.5	13,536.1	14,078.4	14,606.0	15,044.9
Red River Delta	24,753.3	25,864.7	26,756.8	27,583.3	28,315.3	28,884.1
North Central Region	11,328.9	11,529.2	11,758.3	12,025.0	12,338.9	12,638.8
South Central Coast and Central Highlands	15,872.7	16,366.4	16,821.7	17,259.0	17,664.3	17,992.3
Southeast Region	20,995.7	22,006.4	22,715.0	23,200.9	23,485.8	23,587.3
Mekong River Delta	15,791.6	15,942.9	16,082.2	16,152.4	16,126.6	15,982.0

Projections show that the population of most regions increases during 2024-2049, but the growth rate gradually declines over time. Highly urbanized regions such as the Red River Delta and the Southeast Region continue to grow rapidly in the early years, but their growth slows toward the end of the projection period due to declining fertility and changes in migration flows. The remaining regions maintain moderate but lower levels of growth, reflecting their socio-economic characteristics and more limited capacity to attract population. Notably, the Mekong River Delta records the lowest growth, with its growth rate falling sharply and turning negative in the later years, indicating the strong impact of long-term net out-migration.

Figure 2.8: Projected average annual population growth rate of socio-economic regions under the medium variant, 2024-2049



IV. Projected provincial population

Similar to the projections for socio-economic regions, the provincial population projections are provided only up to 2049 (covering a 25-year period).

Table 2.5 presents the projected population size under the medium variant for all provinces. The data show that population growth in most provinces declines gradually across the projection periods. During 2045-2049, 11 provinces record an average annual growth rate of 0.5-0.9%: Lai Chau and Dien Bien (0.9%), Tuyen Quang and Son La (0.8%), Lao Cai (0.7%), Bac Ninh and Quang Trị (0.6%), and Cao Bang, Nghe An, and Ha Tinh, Gia Lai (0.5%). This may be attributed to relatively high initial fertility levels or substantial in-migration in these provinces.

The projections also show that during 2045-2049, six provinces experience negative population growth: Vinh Long (-0.3%); Dong Thap, Can Tho, and Ca Mau (all at -0.2%); and Tay Ninh and An Giang (both at -0.1%). These are mostly provinces assumed to have sharply reduced net out-migration or low initial fertility levels in 2024.

By the end of the projection period in 2049, Hanoi and Ho Chi Minh City remain the two largest urban centers in the country, with populations exceeding 10 million, reaching 10.3 million and 15.3 million people, respectively.

SECTION 3

CONCLUSIONS AND RECOMMENDATIONS

The report on population projections for Viet Nam for the period 2024-2074 provides a comprehensive picture of trends in changes in population size, structure, and distribution over the next half century, while also reflecting Viet Nam's demographic transition. Changes in fertility, mortality, and migration are the three core components of population dynamics that reshape the age structure, sex composition, and the spatial distribution of the population across regions.

The accuracy of population projections depends largely on the appropriateness of the assumptions used. The assumptions applied in these projections are developed on the basis of current and past demographic trends in order to project future developments; thus, population projections are essentially trend-based forecasts. However, in reality, population change is influenced by many social and economic factors, including policies implemented at both central and local levels. The interactions among these factors are highly complex and largely not fully understood. Although, in formulating the assumptions, the National Statistic Office takes into account the objectives of current population-related policies and interventions (for example, targets related to maintaining replacement-level fertility) in order to anticipate trends, it is difficult to fully capture all factors affecting future population change. In addition, when establishing the assumptions, the National Statistic Office assumes that socio-economic conditions remain in a normal state. Under this assumption, unexpected shocks affecting population dynamics, such as wars, famines, or major epidemics, cannot be anticipated and therefore cannot be incorporated into the population projection model.

These limitations should be taken into account when using the projection results for policy formulation.

Viet Nam's population is expected to continue growing over the coming decades, but at a gradually slowing pace, and is projected to reach a peak before transitioning to a phase of slow growth or stabilization. Persistently below-replacement fertility, continued increases in life expectancy, and strong internal migration flows have resulted in an age structure that is rapidly shifting toward population ageing. The projections indicate that the period of the demographic dividend will come to an end in the not-too-distant future, giving way to an ageing and super-ageing population, as reflected in the gradual contraction of younger and working-age groups alongside the rapid expansion of the elderly population.

In addition, the persistence of sex imbalance at birth through the middle of the century will continue to affect the sex composition of the population, particularly among younger age groups and those of reproductive age in the future. The process of urbanization will continue but is expected to slow as the urban population share reaches 50%. Internal migration will remain a key factor reshaping the spatial distribution of the population across regions, reflecting disparities in socio-economic development and local capacity to absorb labor.

Based on demographic trends and the projected changes in Viet Nam's population structure over the period 2024–2074, it is essential to propose appropriate policy directions to enable the country to proactively adapt to the new context. The recommendations below are developed on the basis of evidence from the population projection results, with the aim of supporting central and local policy-making bodies in the formulation of future socio-economic development plans.

1. Take advantage of the favorable population structure and adapt to the aging population.

Viet Nam's population forecasts show that its favorable population age period will end in 2036. Over the next decade, the effective use of the advantages of the population structure is decisive for economic growth and national competitiveness. It is necessary to prioritize strong investment in skill development for the workforce, especially digital skills, vocational skills and technology

adaptation capacity in the context of rapid digital transformation. At the same time, improving labor productivity through the renewal of vocational training contents, expanding retraining and advanced training, promoting research and development and strengthening the application of science and technology in enterprises is an urgent requirement. Along with that, improving working conditions and developing a safe and flexible working environment will contribute to retaining and maximizing the young workforce, increasing the resilience of the economy.

Making the most of the remaining opportunities of the favorable population age period is also an important preparation for the period of rapid aging in the coming decades. Vietnam will enter the “aged” population stage from 2034 and become a "super-aged” country from 2050; The population aged 80 and over is growing rapidly, from about 2 million people in 2024 to more than 15.4 million people in 2074. These changes put enormous pressure on social security, health and care systems. Therefore, it is necessary to build a multi-layered and sustainable social security system; expanding long-term care services, focusing on home care and community-based care models; and effectively take advantage of the role of the elderly in socio-economic development through appropriate forms of employment. The policy also needs to pay special attention to older women – who make up a large share of the elderly –by applying gender-sensitive policy solutions to help older women access care and social protection services equitably, reduce vulnerability, increase the ability to live independently and resilience in advanced age.

At the same time, it is essential to strengthen access to and improve the quality of sexual and reproductive health services, as well as to enhance childcare, nurturing, and early childhood care and education services. These constitute foundational interventions to ensure long-term human development and, at the same time, to enable individuals and couples to realize their fertility intentions. Priority investments should be directed toward the primary level of service delivery, with a particular focus on populations at risk of being left behind, including ethnic minority groups, out-of-school adolescents, and migrants.

In parallel, family support service systems should be further developed, including the expansion of high-quality early childhood education facilities, the promotion of workplace-based childcare models, improvements in child nutrition, and strengthened support for early childhood development. These measures aim to create an enabling environment that ensures children’s holistic development, encompassing physical health, cognitive development, and socio-emotional development.

These elements represent core pillars for ensuring sustainable development of human capital and for strengthening the demographic foundations for the future. Moreover, in the context of declining fertility as a global trend, in addition to using the total fertility rate indicator, it is also necessary to consider alternative indicators to help measure the country's adaptability.

2. Proactively addressing the consequences of sex imbalance at birth

Sex imbalance at birth in Viet Nam has emerged since the early years of the twenty-first century, persisted to the present, and is projected to continue for at least the next five years before gradually declining. However, the consequences of this imbalance are expected to extend over several decades, most visibly reflected in a significant surplus of men over women in marriageable ages.

This imbalance will directly affect families, the basic unit of society, and may contribute to further fertility decline, while also posing potential risks to social stability. Therefore, it is essential to develop and implement timely policy responses to address these consequences over the medium and long term.

3. Developing smart urban systems adapted to demographic transition trends

Viet Nam's urban population is projected to reach 50 per cent by 2045 and further increase to 65 per cent by 2074, in a context of continued fertility decline and rapid population ageing. These demographic shifts require urban systems to be planned and developed in a more flexible and adaptive manner. Policies should prioritize the modernization and expansion of urban infrastructure, ensure equitable access to housing and public services, promote efficient land-use management, improve environmental quality and urban transport, and advance green and smart city models. Evidence-based urban planning informed by demographic trends will be a critical factor in ensuring long-term sustainable development.

4. Strengthening international cooperation to address population-related challenges

In the context of demographic challenges that are increasingly global in nature and closely interconnected with regional trends, Viet Nam needs to strengthen international cooperation in the formulation and implementation of population policies. Collaboration with other countries and international organizations will enable Viet Nam to access international experience, evidence, and effective intervention models for addressing low fertility, population ageing, gender inequalities, and migration management. At the same time, international cooperation contributes to enhancing technical capacity in population projections, policy impact analysis, and the mobilization of financial and technical resources for targeted intervention programmes, thereby improving the quality and effectiveness of population policy implementation at the national level.

5. Improve the population data and statistics system for policy making.

Changes in population size, age structure, and spatial distribution over the coming decades will have far-reaching implications for education, health, employment, social protection, and urban development. As demographic transitions accelerate, Viet Nam needs to strengthen its capacity to use data and projection models in policy formulation and monitoring. Modernizing population–civil registration–migration data systems, ensuring interoperability and information sharing across sectors, and integrating demographic analysis into strategic planning at both national and local levels will help improve policy decision-making and support long-term sustainable development. To ensure effective policy formulation and monitoring, Viet Nam needs to further strengthen a modern, integrated, and interoperable population information and statistical system. A key priority is the development of a national population database that links the population register with sectoral databases on civil registration, health, education, social insurance, and labour and employment, and leverages these data sources to inform macroeconomic and social development policymaking.

A comprehensive and timely data system will contribute to enhancing state management effectiveness and support proactive, evidence-based, and accurate policy decision-making.

APPENDIX 2: COMPONENT METHOD

Population projection by component method is based on the change degree and trend of three factors of fertility, mortality and migration of population together with population quantity and structure by sex and age at a certain time in the past and present to project population quantity and structure by sex and age for different times in the future. Thus, the component method has following advantages:

(1) Provide data by age and sex

(2) Clearly look at the trend of population development components of fertility, mortality and migration. Thanks to composition method, the effect of a given trend can be seen.

(3) Provide more accurate results than other projection methods due to the use of specific models of age and sex structure and fertility, mortality and migration patterns by age.

(4) It is simpler in concept, calculation formula and calculation method than many other methods.

(5) Make the most use of the available data, including information such as family size expectations and desire of couples collected in many national and local sample surveys.

Population projection by composition method use input information as follows:

(1) Structure by sex and initial age (base population);

(2) Assumptions of mortality;

(3) Assumptions of fertility;

(4) Assumptions of migration.

When using the composition method for population projection, projected results can include:

(1) Quantity of population by sex and age;

(2) Population change rates due to fertility, mortality and migration

The process of projection by composition method consists of certain calculation steps repeated for each projection phase, usually 5 years. The steps of composition method are:

Step 1: Calculate number of population aged 5 and over surviving to the end of each projection phase.

In this step, assumptions of mortality in the future, namely the survival coefficients by age, will be used to determine population structure by sex, age and age at the end of projection periods by following formula:

$$ {}_5P^1_{x+5} = {}_5P^0_x \cdot {}_5S_x \quad (2.1) $$

Where:

${}_5P^1_{x+5}$ *: population in the age group (x+5, x+10) at the end of projection period;*

${}_5P^0_x$ *: population in the age group (x, x+5) at the beginning of projection period;*

${}_5S_x$ *: survival coefficients of the age group (x, x+5) during the projection period x = 0, 5, 10...*

In the formula (2.1), ${}_5S_x$ - survival coefficients of the age group (x, x+5) is calculated from the life table as follows:

$$ {}_5S_x = {}_5L_{x+5} / {}_5L_x \quad (2.2) $$

Where:

${}_5L_x$ *: number of survival people in the age group (x, x+5) of the life table;*

${}_5L_{x+5}$ *: number of survival people in the age group (x+5, x+5+5).*

In principle, a population projection is prepared in conjunction with the development program built for a 15-20 year cycle. In this point of view, conducting a component-based projection will be repeated over several five-year cycles.

Step 2: Calculate number of under-5 population at the end of projection period

Number of under-5 persons (0-4 years old) at the end of projection period are number of children born in the projection period alive until the end of projection period. Thus, in order to calculate this figure, initially calculate number of children born during the projection period and then multiply this figure with suitable coefficients.

The number of children born during the projection period is calculated from the fertility rates under fertility assumptions and the average number of women of reproductive age in the projection period and the sex ratio at birth.

a) The average number of women of reproductive age

The average number of women in the age group (x, x+5) in the projection period is calculated by summing up the number of women of that age group at the beginning and the end of projection period and then dividing by 2 (average), by the following formula:

$$ {}_5P_{f,x} = 1/2({}_5P^0_{f,x} + {}_5P^t_{f,x}) \quad (2.3) $$

Where:

${}_5P^0_{f,x}$ *: The number of women of the age group (x, x+5) at the beginning of projection period;*

${}_5P^t_{f,x}$ *: The number of women of the age group (x, x+5) at the end of projection period.*

b) Calculate total number of births during the projection period

Number of children born in the projection period is calculated based on average number of women of reproductive age and age-specific fertility rate of the projection period. Total number of newborn children was calculated by the following formula:

$$ B = 5 \Sigma {}_5P_{f,x} * {}_5ASFR_x \quad (2.4) $$

Where:

${}_5ASFR_x$ *: age-specific fertility rate of women in the age group (x, x+5) in the projection period.*

c) Calculate number of births for each sex

Since the number of under-5 girls (0-4 years old) at the end of the projection period is the number of girls born in the projection period alive until the end of the projection period. So, in formula (4), the age-specific fertility rate (ASFR) of women denotes for each sex, when multiplying the average number of women by the ASFR of given sex, we will have the number of births by that given sex. If the age-specific fertility rate of women is calculated for both sexes, then after calculating the total fertility, it must be separated by sex. This can be done by using the sex ratio at birth.

Assuming : B Total children were born;

B_m Number of newborn boys;

B_f Number of newborn girls;

SRB Sex ratio at birth, which is defined by number of boys to 100 girls.

When:

$B_m + B_f = B$ và $B_m/B_f = SRB$, so:

$B_m = B*SRB/(1+SRB)$

$B_f = B*1/ (1+SRB)$ (2.5)

d) Determining under-5 population by each sex

After determining the number of births in the projection period by sex, the under-5 population can be easily calculated at the end of the projection period thanks to the survival coefficient from birth to 0-4 years old (ability to live from birth to the age of 0-4). The survival coefficient from birth to 0-4 years old is calculated by dividing the number of people alive in the age group of 0-4 years old the life table (5L0) by 5 times of the initial number of births in the life table (l0):

$$ {}_5P_{m,0} = B_m * {}_5L_{m,0} / 5*l_0 $$

$$ {}_5P_{f,0} = B_m * {}_5L_{f,0} / 5*l_0 \qquad (2.6) $$

Trong đó:

${}_5P_{m,0}$ *: Number of boys aged 0-4 at the end of projection period;*

${}_5P_{f,0}$ *: Number of girls aged 0-4 at the end of projection period;*

${}_5L_{m,0}$ *: Number of people alive in the age group of 0-4 years old of the male life table;*

${}_5L_{f,0}$ *: Number of people alive in the age group of 0-4 years old of the female life table;*

l_0 *: Number of initial births of life table (base of life table);*

Step 3: Project number of net migration

Age-specific net migration (equaling number of in-migration minus number of number of out-migration) can be estimated by multiplying age specific net migration rate with agespecific population at the end of projection period estimated in the Step 1 and Step 2.

Number of net migration for each sex is determined as follows:

$$ {}_5M_{m,x} = {}_5P_{m,x} * {}_5ASNMR_{m,x} $$

$$ {}_5M_{f,x} = {}_5P_{f,x} * {}_5ASNMR_{f,x} \quad (2.7) $$

Trong đó:

${}_5M_{m,x}$ *: Number of net migration of males at the age x in projection period;*

${}_5M_{f,x}$ *: Number of net migration of females at the age x in projection period;*

${}_5ASNMR_{m,x}$ *: Age-sex-specific net migration rate;*

Finally, total population at the end of projection period is calculated by summing up population aged 5 and over of each sex as calculated in the Step 1 and under-5 population of each sex as calculated in the Step 2 and number of net migration during period as calculated in the Step 3.

APPENDIX 3: WHIPPLE AND MYER INDICES

1. Whipple index

1.1. Concept

Whipple's index (age heaping index) is designed to measure the preference or dislike of certain numbers when reporting age. Usually, it is calculated to measure the preference for ages with the ending number of 0 and 5. This index is determined by the correlation between the total population aged 25, 30, 35, 40, 45, 50, 55 and 60 with 1/5 of the population at all ages from 23 to 62 years old.

1.2. Calculation formula

$$\text{Whipple's index} = \frac{P_{25}+P_{30}+P_{35}+P_{40}+P_{45}+P_{50}+P_{55}+P_{60}}{1/5x\,(P_{23}+P_{24}+P_{25}+P_{26}+...+P_{59}+P_{60}+P_{61}+P_{62})} \times 100$$

Whipple's index has a value ranging from 100 to 500. If the Whipple's index equals to 100, there is no age heaping with the ending number of 0 and 5; if the Whipple's index equals to 500, meaning that everyone reports their age ending in 0 and 5. If there is undesire or dislike with the ending number of 0 and 5, the Whipple's index will be less than 100.

1.3. Evaluation classification

To classify the quality of age reporting by Whipple's index, the following standards are used (see United Nations, 1990; Iwunor, 1993):

- < 105: Very good
- 105 to 110: Fairly good
- 110 to 125: Good
- 125 to 175: Poor
- > 175: Very poor

2. Myer index

2.1. Concept

In order to study age heaping at numbers ending from 0 to 9, the Myer index is used. This index reflects whether respondents like or dislike reporting age at a certain number ending between 0 and 9.

2.2. Calculation method

Myer index is calculated by the following steps:

Step 1: Arrange age distribution by each year

Make a table of 20 columns, including the first column referring to age ending between 1 and 9 of the population, the remaining columns referring to population by age group. Thus, each column is the population at the age ending in 0, 1, 2, 3, 4, 5, 6, 7, 8 and 9; each row is the population at the ages between 10 and 19, 20 and 29, 30 and 39, 40 and 49, 50 and 59, 60 and 69, and 70 and 79.

Step 2: Accrue the ages with the same ending number (from column (2) to column (8) and fill in column (9)) by each row from 0 to 9 respectively. This is done consecutively for all rows, even total row.

Step 3: Weighting the total numbers in step 2 and summing up results to get "mixed" population. The weights are put in the columns (12) and (15).

In column (12), the weight 1 correspond to the row of age ending in 0, the weight 2 correspond to the row of age ending in 1, … the weight 10 correspond to the row of age ending in 9.

In column (15), the weight 9 is equivalent to the row of age ending in 0, the weight 8 correspond to the row of age ending in 1, … and the weight 0 is equivalent to the row of age ending in 9.

Move data in the column (9) into the column (11), move data in the column (10) into the column (14) and conduct weighting by multiplying the column (11) with the column (12) and fill the results in the column (13). Similarly, multiply the column (14) with the column (15) and fill the results in the column (16). Finally, summing up the weighted columns and fill the results in the column (17).

Step 4: Transform result distribution in Step 3 (column 17) to percentage by dividing data in each row by total and multiplying with 100.

Step 5: Compare percentage deviation from 10 by taking results in each row of the column (18) to minus 10 and fill in the column (19).

Take absolute values in the column (19) and fill in the column (20).

Step 6: Calculate Myers index by summing the absolute values of deviations from 10 and then dividing by 2 (taking the total row of the column (20) divided by 2)

2.3. Evaluation classification

The General Myers index ranges from 0 to 90. The smaller the Myers index indicates more accurate age reporting (less age heaping).
